You get more microscope for your money when you buy Meopta

Meopta microscopes surprise even the experts. They're such finely made precision instruments but cost so much less than you'd expect. Every Meopta microscope is designed to meet the highest optical standards—Meopta objectives are especially noted for superlative quality. Yet you pay less for a Meopta than for any comparable instrument. It's not surprising that so many far-sighted scientists have already chosen Meopta microscopes for their teaching and research laboratories.

Microscope C36 BI
Meets all the requirements of scientific and research workers. Binocular microscope with built-in mechanical stage, integral Kohler lighting and photomicrography tube Standard optical equipment includes six achromatic objectives, three pairs of eyepieces and a N.A. 1.4 condenser. Magnifications from 43x to 1,800x

HIGHLY SUCCESSFUL ULTRA-MICROTOME

The outstanding success of this microtome for electron microscopy has resulted in rapidly-increasing sales to discriminating users, in both the New and Old Worlds, and the instrument is right at the top of its class. This is due to its unsophisticated design, simplicity and reliability in operation, plus skill and workmanship in the Cambridge tradition during manufacture.

Some of the outstanding advantages:

▮ Strip hinge suspension—no friction or backlash ▮ Mechanical specimen advance—accurate calibration of section thickness ▮ Fine adjustment of automatic advance—steps of 5mμ from zero to 150mμ ▮ Full range of knife adjustments—tilt, traverse, rotation and micrometer advance ▮ Large specimen travel 0·1 mm. by automatic advance ▮ Large specimen area—cuts 3 x 4 mm. if needed.

The Cambridge Ultra-Microtome is gravity-operated, and has no motor to cause vibration

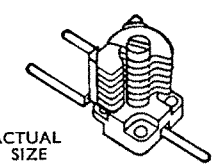
OXLEY DEVELOPMENTS CO. LTD.

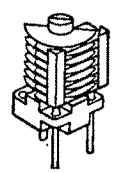
OXLEY

SUBMINIATURE AIR DIELECTRIC TRIMMERS



A continuous study in the laboratory and in the field has resulted in a further development in Oxley subminiature air dielectric trimmers, the rotor and the stator both being made of solid metal.

This results in :—



(1) The elimination of practically all soldered joints.
(2) A positive increase in mechanical rigidity and improved electrical stability.
(3) A high order of consistency in capacity.

In other respects the trimmers retain all those facilities which have made them the inevitable choice of professional equipment in which reliability is the dominant requirement.

irradiation on the synthesis of bacteriochlorophyll. Fifty-ml. Esbach dishes covered with a glass plate were used as culture chambers. The other experimental conditions are described elsewhere[7].

If dark-grown cultures are transferred to conditions of anaerobic light-growth, synthesis of chlorophyll starts only after irradiation with far-red or blue or green (Fig. 1). Under the experimental conditions, we have observed a relation between light-intensity and the amount of bacteriochlorophyll synthesized in 48 h (Fig. 2). These two facts suggest that light controls the synthesis of bacteriochlorophyll through photosynthesis. In contrast to the observations of Wolken[8] concerning the synthesis of chlorophyll in *Euglena*, light which is absorbed by *proto*bacteriochlorophyll is not utilized for synthesis of bacteriochlorophyll. Further, we tested the effect of pre-illumination with low light intensities of different wave-lengths; but we could not detect any influence of other pigment systems different from bacteriochlorophyll and carotenoids.

This work was supported by the Deutsche Forschungsgemeinschaft.

Similar Effects of Various Neutral Solutes on the Survival of *Aerobacter aerogenes* and of Red Blood Cells after Freezing and Thawing

Aerobacter aerogenes from continuous culture is killed by slow freezing in buffer or by freeze-drying. Rapid freezing in liquid nitrogen results in 50 per cent survival if the organisms are suspended in distilled water, and almost complete survival if they are suspended in 10 per cent glycerol. Ten per cent solutions of some other polyhydroxy-compounds, sugars or of polyethylene glycol protect equally well[1]. The work recorded here extends the investigation to other, mainly non-hydroxylic, compounds. Like the sugars, these had already been tested on human red blood cells subjected to relatively slow freezing (various workers, references below) and it seemed possible that the response of *A. aerogenes* would not be very different from that of red cells.

Table 1. Effect of Aqueous Solutions on Freezing Damage to *Aerobacter aerogenes* from Continuous Culture compared with Their Effect on Freezing Damage to Red Blood Cells

Solute	Conc. (%)	Survival (%)	Protection	Protection (red cells)

Ovalbumin	10	97, 96, 95	Complete	Not tested

(aug.), augmentative.

The experimental procedure for freezing in liquid nitrogen and measuring viability has been described[1]. Apart from the higher rate of freezing, the main difference between the present system and that normally used in experiments on red cells is that distilled water and not saline had to be used, because *A. aerogenes* is very sensitive to salt on freezing. The solutes were at 10 per cent strength (v/v for liquids, w/v for solids) except when this concentration was found to be toxic at room temperature; in such cases the highest tolerated concentration was used.

The results are shown in Table 1; each test includes controls using distilled water which gave viabilities very near to 50 per cent, except for acetone when the controls were a little low. The unfrozen populations were uniformly 95–99 per cent viable. The effect of each solute on the hæmolysis of red cells by freezing and thawing is also given, with a reference; the concentrations used are assumed to be optimal, generally between 10 and 20 per cent for the good protectors. *A. aerogenes* was protected from freezing damage by very much the same compounds as those which protect red cells despite differences in the technique used to determine response of these systems. Another way in which *A. aerogenes* resembles red cells is its sensitivity to cold shock[2], which is, however, observed only with bacterial cells in the logarithmic phase of growth and not with those from continuous culture; with red cells special conditions are also required[3].

It is of particular interest that *A. aerogenes* is protected by the same non-penetrating polymeric solutes which protect red cells, and these results may help in resolving the present controversy regarding the role of intracellular salts in the lethal effects of low temperatures. It should also be noted that the best low-molecular weight protectors are, under other conditions, particularly lethal to gram-positive bacteria such as micrococci, and it is believed that this is connected with the strong solvent action that such compounds can exert on the cell wall, when the solution is sufficiently concentrated[4].

CYTOLOGY

Multinuclearity of Osteoclasts

The origin and function of the multinuclear osteoclast cell are of continuing interest among contemporary investigators, and have a long history among investigations on amphibian regeneration[1,2].

The reported origin of this cell is varied[3], with reticulocytes, osteoblasts, and osteocytes receiving complete or partial support from Bloom *et al.*[4] and Tonna[5], whereas a hæmatogenic origin from mononuclear leucocytes is recommended by Fishman and Hay[1] and others.

The phagocytic activity of osteoclasts[3,6] lends itself well to this cell, being considered with other macrophages as a

Fig. 1. Of the multinuclear osteoclasts (*Os*) illustrated, one clearly appears to be in the process of ingesting an osteocyte (*O*). The cytoplasm of the osteoclast is vacuolate and contains granules. The cell surface adjacent to the bone (*B*) in a Howship's lacunus appears to be fibrillar (from ref. 6, Fig. 2). (Triple stain, × 200)

member of the reticuloendothelial system of Aschoff[7]. Thus the osteoclast may originate from mesenchymally derived osteoblasts in mammals[5] and in birds[4], or from mononuclear leucocytes in amphibians[1]. Regardless of the exact origin of osteoclasts among the various species studied, these cells acquire a number of nuclei without normally synthesizing deoxyribonucleic acid nor revealing mitotic activity[5]. Therefore one may ask, What is the source of the typically large numbers of nuclei of the osteoclast?

The osteoclast described by Fishman and Hay[1] contains radioactive nuclei (tritiated thymidine) derived from previously labelled mononuclear leucocytes, and numerous unlabelled nuclei. The source of these latter nuclei may be from previously unlabelled mononuclear leucocytes fusing with labelled cells in forming the osteoclast[1].

However, we must consider the ample evidence of phagocytic activity demonstrated by these cells[3,6]. Bloom *et al.*[7], in birds and others in mammals[3], have reported the incorporation of osteocytes into the osteoclast. We have also observed this latter activity (Fig. 1) in the amphibian, *Diemictylus viridescens* (*Triturus* v.)[2]. Therefore we believe that a large share of the nuclei found within the osteoclasts are derived from osteocytes freed from their lacunæ through mineral erosion.

Meiotic Investigations in Man

It is widely believed that meiotic investigations in man are only possible on freshly fixed testicular biopsies, or on fœtal ovary. As these investigations provide the only method for the detection of such aberrations as paracentric inversions, reciprocal translocations involving pieces of similar size, and small deficiencies of long chromosome arms, and as these may well be very common in man in view of both the frequency of infertility, and of the extreme variability in chromosome morphology evident at mitosis, any method of obtaining relevant data on a population scale would be of great value. Although remarkable progress, largely as a result of the technical improvements following the use of air drying[1] and the extension of the culture techniques evolved for bone-marrow[2] to blood[3], has followed the publication, seven years ago, of a technique for handling cell suspensions from mammals[4], no comparable progress, either in technical development or observational opportunity, has followed the work on human meiosis published by the same authors the same year[5].

Nor have there been any major advances in the past four years which either simplify or accelerate mitotic investigations on post-mortem material; these are still dependent on the skilled and laborious ritual of fibroblast culture. Lymphocyte cultures obtained by briefly dipping an intact thymus in 50 per cent alcohol, rinsing in sterile saline, breaking up in culture medium containing serum and phytohæmagglutinin, and processing after three days, are simple if the thymus is obtained shortly after death; but this is rarely practicable in most countries. Although restricted to adult males, and excluding the very aged and most cases with sex-chromosome anomalies, the disclosure of meiosis, if feasible, would provide a simple post-mortem method of examining the basic caryotype, either routinely or in selected diseases. Such observations may be supplemented by nuclear sexing; although post-mortem buccal smears are unpleasant to take and may be difficult to interpret, excellent preparations showing Barr bodies which are larger and clearer than those in oral epithelium, and present in the great majority of cells in the normal female, may be obtained by making smears from the bladder.

We wish to report our failure to obtain satisfactory preparations of meiosis from post-mortem material, but to point out that numerous cells in zygotene are readily found up to three days after death, provided refrigeration is adequate. We believe that our failures are technical and will be resolved by methods which we have so far failed to elaborate.

Numerous preparations, such as that shown, may be obtained by extruding the contents of a tubule, incubating in hypotonic citrate, fixing by adding excess acetic alcohol, resuspending in acetic alcohol, and air drying. A suspension of cells from inside the tubules may be made by putting a piece of testis into 1 per cent sodium citrate in a plastic bag, cutting into fragments with a scissors, and squeezing between the fingers. Fixation may also be carried out by centrifuging through increasing concentrations of acetic acid in successive layers.

Although inadequate to reveal abnormalities, unless fortuitously well placed, the preparations show nuclear structures of interest. A globular structure which stains

Fig. 1. Meiosis 48 h *post mortem*. The nucleolus is the pale oval structure at bottom right

lightly with methylene blue, and resembles the large nucleolus of the spermatocyte, is not intimately related to the chromosomes: some cells have two smaller nucleoli. A densely staining structure intimately related to several chromosomes is usually evident. Variations in staining of the paired chromosomes appear to be identical in both strands. Satellites are sometimes seen and appear unrelated to any other structure. A small chromosome frequently lies at the periphery and could be the *Y*. If this peripheral localization is found in mitotic cells the possibility that selective loss of the *Y* chromosome might arise after fixation deserves consideration.

Diverse experimentation with this inexhaustible supply should provide techniques from which population investigations comparable with those conducted on *Drosophila* could be carried out.

GENETICS

Incidence of Pseudocholinesterase Variants in Australian Aborigines

There are now known to be a number of genetically determined variants of the human serum enzyme pseudocholinesterase[1–5], of which the most frequent in Britain are the 'typical' and 'atypical' variants. Homozygotes for the 'typical' variant amount to about 96 per cent of the population, and heterozygotes to about 4 per cent. 'Atypical' homozygotes are only seen once among several thousands. The different pseudocholinesterase types are recognized by determining the degree of inhibition of the enzyme by dibucaine ('Nupercaine') following the method of Kalow and Genest[1], the percentage inhibition being called the dibucaine number. The other pseudocholinesterase variants are extremely rare and they are also discovered in the first instance by their less than normal inhibition by dibucaine, with one exception, the 'silent' variant[4] which in the homozygote results in complete absence of enzyme activity.

* In parentheses: before correction for first degree relationship.

So far, the incidence of the typical/atypical heterozygote has been found remarkably alike in very different populations: Canadian[6], British[7], Greek[7], Portuguese[7], Moroccan (Jewish)[7], Berbers[7], Czechs[8] and Germans[8].

We have recently examined the sera from 104 Aboriginal Australians. Twelve were first-degree relatives and six were therefore taken out to obtain a less-selected sample. In the remaining 98, one heterozygote was found. This does not represent a striking difference from surveys made in other parts of the world, and 'atypical' pseudocholinesterase remains an inherited characteristic with remarkable uniformity of incidence in racially widely different populations.

Harris, Hopkinson, Robson and Whittaker[9] have recently described an isoenzyme of pseudocholinesterase which is recognized by electrophoresis at *p*H 6. It is genetically independent from the 'typical' pseudocholinesterase and its variants. It was found in 5 per cent of 248 unrelated British individuals. We have confirmed the occasional occurrence of this isoenzyme in Europeans, but have not found it in these 104 Australian samples.

A Case of Somatic Polyploidy

Natural alterations in the number of chromosome sets appear to be uncommon among the somatic tissues of animals. Somatic haploidy has been claimed to occur in the micromeres of sea-urchin embryos[1], and in the tail mesenchyme of tadpoles[2]. The former case was quickly denied[3], while the latter is also better interpreted as the pairing of homologous chromosomes. Polyploidy is well known in mammalian liver and in various tumours, but rarely in other tissues.

In the course of an investigation of the frequency of nucleolar fusion during the development of *Xenopus laevis*[4], the following evidence was found of polyploid nuclei in the notochord. The notochord cells do not divide while differentiating at neurula stages to form a vacuolated syncytium. Mitosis is only resumed shortly before the time of hatching. The resulting interphase nuclei in the notochords of feeding tadpoles are more variable in size than is usual for one tissue. As many as six nucleoli have been seen in these nuclei, although a maximum of two nucleoli per nucleus is found in other tissues, and in the notochord itself of unhatched embryos. Such numbers of nucleoli could be explained theoretically as the result of polyploidy, or as the production of 'accessory nucleoli' by normally latent nucleolar organizers[5]. The nucleolar counts might thus be interpreted as indicating either some tetraploid and octoploid nuclei, or up to four accessory nucleoli. These explanations have been tested by the use of heterozygous mutants which form only one nucleolus in each of their nuclei[6]. The mutants are fully viable and possess the full diploid number of chromosomes[7]. The notochord nuclei of these mutants would be expected to contain up to three nucleoli

Table 1. Frequency Distribution of Notochord Nuclei containing 1–6 Nucleoli

Genotype and specimen	No. of nucleoli 1	2	3	4	5	6	Total count	Minimum percentage of polyploidy
Wild 1	21	48	21	7	2	1	100	31
Wild 2	28	50	16	5	0	1	100	22
Wild 3	29	47	16	5	2	1	100	24
Wild 4	34	55	8	2	1	0	100	11
Mutant 1	69	29	2	0	0	0	100	31
Mutant 2	66	34	0	0	0	0	100	34
Mutant 3	70	29	1	0	0	0	100	30
Mutant 4	67	31	2	0	0	0	100	33

if polyploidy occurs, or up to five nucleoli if some of them were produced by latent organizers. Nucleolar counts from the notochords of four wild-type and four mutant feeding tadpoles are shown in Table 1; their comparison fits the expectation for polyploidy. Some polyploidy is certainly obscured by nucleolar fusion in these counts, as indicated by the odd numbers of nucleoli in wild-type specimens, and by the inequality in size of the nucleoli in some nuclei. Probably well over 30 per cent of the notochord nuclei become polyploid.

The occurrence of polyploidy without hazard to cell-type in this tissue, mammalian liver and experimentally produced polyploid animals, suggests that polyploidy is only an incidental phenomenon of tumours. The common factor in tumours and other cases of spontaneous polyploidy may well be that mitotic activity is resumed after a prolonged interphase of the differentiated cell, when the cellular resources are perhaps incomplete or unbalanced.

VIROLOGY

Nicotinamide-adenine Dinucleotides, Adenosine Diphosphate and Adenosine Triphosphate Content of Tissues infected by Tobacco Mosaic Virus

The physiology of virus-infected plant tissues is of interest in that an understanding of the processes underlying the development of disease symptoms is dependent on a knowledge of changes in the host tissue metabolism induced by virus-infection. An approach to this problem is a consideration of nucleotide-levels in tissues infected by virus. The formation of tobacco mosaic virus (TMV) may give lower nucleotide-levels in the host tissue as a result of the utilization of nucleotides in virus-ribonucleic acid synthesis. This is of particular significance with regard to the adenosine nucleotides, adenosine diphosphate (ADP), adenosine triphosphate (ATP), nicotinamide-adenine dinucleotide (NAD) and nicotinamide-adenine dinucleotide phosphate (NADP), all of which are concerned in the regulation of the intermediary metabolism of the host-tissue[1].

Some possible effects of virus infection on the levels of the compounds in the host-tissue have already been discussed[2]. Moreover, tissues systemically infected by TMV have a lower rate of respiration than comparable healthy tissues[3,4]. This may be the result of changes in nucleotide-levels following TMV-infection[2]. It seems probable that some decrease in nucleotide-levels takes place in TMV-infected tissues as tobacco callus tissue systemically infected by TMV shows a lower concentration of acid-soluble organic phosphorus compounds[5]. In the investigation recorded here the concentrations of NAD, $NADH_2$, NADP, $NADPH_2$, ADP and ATP were determined in tobacco callus tissue cultures systemically infected by TMV.

Table 1. Nicotinamide-Adenine Dinucleotide and Nicotinamide-Adenine Dinucleotide Phosphate Content of Tobacco Callus Tissue Cultures infected by TMV

	μgm/100 mg dry weight	
	Healthy tissue	TMV-infected tissue
NAD	3·8 ± 0·07*	12·0 ± 0·80
NADP	1·6 ± 0·09	0·6 ± 0·002
NADH	0·9 ± 0·01	0·5 ± 0·008
$NADPH_2$	0·5 ± 0·001	0·6 ± 0·006
Total	6·7	13·6

* Mean of four determinations ± *S.E.*

Table 2. ADP and ATP Content of Healthy and TMV-infected Tobacco Callus Tissue Cultures

	μmoles × 10^3/100 mg dry weight					
	Experiment 1		Experiment 2		Experiment 3	
	Healthy	Virus	Healthy	Virus	Healthy	Virus
ATP	5·5	1·4	6·3	1·6	6·4	4·0
ADP	2·3	1·7	3·8	1·7	3·5	1·2
ATP + ADP	7·8	3·1	10·1	3·3	9·9	5·2

Healthy and virus-infected conditioned callus tissue of *Nicotiana tabacum* type White Burley var. Judy's Pride were sub-cultured on a modification of the medium of Morel[6] as suggested by Kassanis[7] containing 0·5 g calcium nitrate, 0·5 g dihydrogen potassium phosphate, 0·125 g potassium nitrate, 0·125 g magnesium sulphate, 20 g glucose, 0·5 ml. Bertholet's solution, 10 mg cysteine hydrochloride, 1 mg thiamine and 5 g of agar per litre. Sub-cultures were made with pieces of tissue approximately 50 mg fresh weight and grown on 15 ml. of media in tubes (15 cm × 3 cm) sealed with polythene and kept at a constant temperature of 25° C with a continuous light intensity of 200 ft.-candles at the level of the culture.

Nicotinamide-adenine dinucleotides were extracted from 1 gm fresh weight samples of tissue. NAD and NADP were extracted by an acid medium of 5 ml. of 0·1 M *tris*-hydrochloric acid buffer *p*H 8·2, 1 ml. N hydrochloric acid and 2 ml. water. $NADH_2$ and $NADPH_2$ were extracted by an alkaline medium, 5 ml. *tris*-hydrochloric acid buffer 1 ml. N sodium hydroxide and 2 ml. of water. The extraction medium was contained in a glass Potter–Elvehjem homogenizer immersed in a bath of boiling water. The tissue was dropped in and heated for 30 sec, homogenized for 1·5 min and then rapidly cooled by immersion in a freezing mixture of dry-ice and ethanol. The extracts were thawed and centrifuged at 20,000*g* for 15 min in a refrigerated centrifuge. The supernatants were decanted; the *p*H of the alkaline extracted adjusted to 8·0 and that of the acid extract to 7·0 by dropwise addition of alkali or acid in the cold. The nicotinamide-adenine dinucleotide content of the extracts was determined immediately by the colorimetric method of Slater and Sawyer[8]. NAD, $NADH_2$, NADP and $NADPH_2$ (Sigma purest grade) were tested for purity by the usual spectrophotometric methods[9] and used for constructing calibration curves for the method of Slater and Sawyer and determining the percentage recovery of nucleotides added to the extracting medium. They were added at ten times the endogenous concentration to 1-g samples of healthy tobacco tissue and the extraction procedure carried out as before. The percentage recovery of added nicotinamide-adenine dinucleotides was NAD 109, NADP 100, NADH. 90, $NADPH_2$ 100.

Adenosine nucleotides were extracted from 1-g fresh weight samples of tissue by homogenizing with 10 ml. o 0·2 N perchloric acid in the cold. A complete extractio was obtained as increasing the acid concentration to 2·0 N failed to extract further ATP. The perchloric acid wa neutralized by N potassium hydroxide in the cold and th

potassium perchlorate precipitate removed by centrifugation. The ATP content of this extract was determined immediately by the luciferin–luciferase method of Strehler and McElroy[10]. The enzyme was extracted from dried firefly tails (Schwartz Bioresearch, Inc.). The light emitted when this enzyme system comes into contact with ATP was measured in a fluorimeter. The reaction mixture contained 0·2 ml. of 0·25 M glycyl–glycine buffer *p*H 7·0, 0·1 ml. of 0·1 M magnesium sulphate, 0·2 ml. of enzyme and 1·0 ml. of the solution for assay rapidly injected and the maximum light flash measured. ATP (Sigma, 99 per cent pure) was used to calibrate the instrument.

ADP was determined in the extracts by conversion to ATP using the enzyme ATP : creatine phosphotransferase which catalyses the reaction $ADP + Cr \sim P \rightleftharpoons ATP + Cr$. The ATP was then determined by the luciferin–luciferase method. 2·6 ml. of the neutralized perchloric acid extract was incubated at 37° C for 1 h with 0·52 ml. of 0·25 M glycyl–glycine buffer *p*H 7·0; 0·26 ml. of 0·1 M magnesium sulphate; 0·52 ml. creatine phosphate solution, stock solution containing 0·3 μmole/ml. in buffer *p*H 7·0; 0·26 ml. of ATP : creatine phosphotransferase (L. Light and Co.), stock solution containing 1 mg/ml. in buffer *p*H 7·0. The enzyme was inactivated by immersion of the incubation mixture in a boiling water bath and 1 ml. aliquots taken for ATP determinations.

The results given in Table 1 show that TMV-infected tobacco callus-tissue contains increased amounts of nicotinamide-adenine dinucleotides. Thus, decreased levels of NAD or NADP will not account for the lower respiration rate in tissues systemically infected by TMV. It also seems probable that formation of TMV does not occur at the expense of nicotinamide-adenine dinucleotide precursors. Although virus infection sometimes results in increased dehydrogenase activity in the tissues[11,12] the increased amount of NAD in the virus-infected tissue actually results in an increase in the NAD/NADH ratio so respiration is not limited by an accumulation of reduced nicotinamide-adenine dinucleotides in the tissue. Occasionally small sections of the TMV-infected tobacco callus tissue turn green. These green tissues showed increased amounts of NADP containing 1·2 μg per 100 mg dry weight.

The results presented in Table 2 show that in tobacco callus tissue infected with TMV there is a decrease in both ADP and ATP, there being less than half of that present in healthy tissue. This decrease may be the result of incorporation of ADP or ATP in virus-ribonucleic formation. The decreased availability of ADP is probably the reason for the lower respiration rate of the virus-infected tissue although further work is required to establish definitely this point.

It is not intended that results obtained with tobacco callus tissue infected by TMV should be taken to apply to other virus host-tissue systems without adequate consideration being given to the physiological state of the tissue and structure of the virus. Even with systemic TMV-infection of *Nicotiana tabacum* leaves the situation is completely different from systemically infected tobacco callus tissue. The presence of chloroplasts in the cell enables a supply of ATP to be generated by photosynthetic phosphorylation but the possibility of compartmentation is greater. Thus, the relationship between ATP as an energy source in virus synthesis and ADP or ATP as a component of virus RNA is certain to be more complex. The different response of different tissues to the same virus is well illustrated by experiments with *Nicotiana glutinosa* leaves showing local lesions induced by inoculation with TMV. These leaves, unlike tobacco callus tissue, show an accumulation of $NADH_2$ and $NADPH_2$ (ref. 13). This result, taken together with the increased respiration rate of these leaves following TMV-induced lesion development[14], may mean that in the tissues the rate of respiration is no longer limited by the availability of ADP but by reoxidation of reduced $NADH_2$ and $NADPH_2$. Further work is in progress to attempt to relate these changes in the intermediary metabolism of the host-tissue to the development of disease symptoms and virus multiplication.

We thank Dr. B. Kassanis for providing the tobacco-callus tissue cultures, and the Department of Scientific and Industrial Research for a grant for equipment.

Interaction of Vaccinia Virus and Cells in Primary and Continuous Culture

Vaccinia virus has a wide host-range, both as regards cell type and animal species. The purpose of the present communication is to describe some differences in the reaction of cells in primary and continuous culture to infection with a vaccine strain of the virus.

Stock virus was prepared from infected chorio-allantoic membranes after three passages of a calf lymph preparation of the LaPine strain No. 472 in embryonate eggs. Details are given elsewhere[1].

Primary cell cultures examined were a fibroblast type, from lung tissue of *ASW/SN* suckling mice 2–3 weeks old, an epithelial type, from kidney tissue of the same animals, and a macrophage type from peritoneal exudate cells of adult animals of the same inbred strain.

Cell lines examined originated from human amnion (*FL*), human carcinoma (*H.Ep.* No. 2) and monkey kidney (*MK*).

Mouse kidney and lung tissues were trypsinized at 4° C, using an active enzyme preparation as suggested by Wallis *et al.*[2]. Fractions taken at 15-min intervals were pooled, and the resulting cell suspension was centrifuged at 800 r.p.m. for 30 min. The cells were then washed by a similar centrifugation in calcium and magnesium-free phosphate buffered saline (*p*H 7·4). The final sediment was diluted 1 : 40 and 1 : 70 for lung and kidney cells, respectively, in a medium consisting of 9 parts by volume of a solution of 0·5 per cent lactalbumin hydrolysate, 0·1 per cent yeast extract and 0·5 per cent glucose in Earle's balanced salt solution, and 1 part of pooled calf serum (*M*). One-ml. aliquots of lung cell suspension, and 1·5-ml. aliquots of kidney cell suspension, were then seeded into 16 × 125 mm Leighton tubes with flat surface dimensions 11 × 37 mm (*LT*). Confluent cell sheets were obtained in 4–7 days.

Macrophage cultures were prepared as described previously[3], with the following modification: the peritoneal exudate was collected by injecting 3 ml. of medium *M* containing 5 units of heparin per ml. into the peritoneal cavity and aspirating the resulting turbid suspension. The cell concentration was adjusted to 4×10^6 per ml., and 1 ml. aliquots were seeded into *LT*. Cultures were ready for inoculation with virus in 2–3 days.

One-week-old cell line stock cultures, grown in milk dilution bottles in medium *M*, were collected by treatment with 'Versene'. After sedimentation, cells were resuspended in medium *M* to a concentration of $1·5 \times 10^5$ cells

per ml., and 1-ml. aliquots of the suspension were seeded into *LT*. Monolayer cultures were obtained in 4–6 days.

In all primary and cell line cultures, the average cell population per tube at the time of inoculation with virus was about 1×10^6.

Table 1. Comparative Yields of Virus in Different Cell Types at Various Time Intervals after Inoculation with Vaccinia Virus (LaPine Strain No. 472) at a Multiplicity of 10 P.F.U./Cell

Cell culture	Average yield in P.F.U./cell at h: 3	8	21	29	53	77
(1) Primary-mouse (*ASW/SN*)						
Kidney-epithelial	0·01	0·01	0·09	0·3	5·3	6·3

Human carcinoma (*H.Ep.* No. 2)	46	380	2·3	310	0·19	90
Monkey kidney (*MK*)	54	410	3·3	390	0·23	120

Infectious virus was assayed by the plaque technique in *H.Ep.* No. 2 cells grown in short Leighton tubes (16 × 80 mm) with increased flat surface dimensions (11 × 55 mm), using a liquid medium. The technique, described in detail elsewhere[4], was modified in two respects: plaque assays were routinely carried out using 2-day-old cultures seeded with 1·5 ml. aliquots of a suspension containing $2{\cdot}5 \times 10^5$ cells per ml., and the cultures were maintained in medium *M* with 5 per cent calf serum.

In one series of experiments cultures were exposed for 1 h to 0·5 ml. of a virus suspension, calculated to give a multiplicity of infection of 10 plaque-forming units per cell. After removal of inoculum, cultures were washed five times with phosphate-buffered saline, fed with medium *M*, and incubated at 36° C. They were then examined at various time-intervals for cytopathic effect and infectious virus. For the latter purpose, 2 tubes of each type of culture were withdrawn at each time-interval and the cells were scraped into the medium. The resulting suspension was quick-frozen and stored at − 65° C. Before titration for virus content, samples were thawed in a water bath at 36° C, transferred to cellulose nitrate tubes, and exposed for 5 min to sonic energy generated by a 200-W, 10-kc./s, Raytheon magnetostrictive oscillator. Medium and cells were pooled before assay for infectious virus since, in the cell systems herein studied, as in those described previously[1], most of the virus was found to be cell-bound.

Cell damage was first observed as early as 3 h post-infection in all the cell line cultures, as well as in the macrophage cultures. In the primary fibroblast cultures it was more delayed, first becoming apparent about 5 h later. In all these cultures, damage began simultaneously in all the cells, and became maximal in 24–48 h. In contrast, primary mouse kidney cultures exhibited only focal lesions for several days, complete destruction of the cell sheets taking about a week.

When cultures were examined for virus content, striking differences in yield were observed, as summarized in Table 1. The macrophage cultures reacted in a unique manner by exhibiting a progressive decrease in the titre of infectious virus. This extends a previous observation on the diminishing titre of cell-free virus in macrophage cultures from random-bred mice[3]. Whether these findings point to an abortive infection leading to the formation of immature virus, or reflect the gradual inactivation of the virus originally taken up by the cells, may be resolved by electron and fluorescent microscopic studies now in progress.

All other cultures supported virus proliferation though at different rates and to varying degrees. In the cell line cultures, the latent period was short, first increase in virus being noted in 8 h. Virus yields amounted to 130–330 plaque-forming units per cell after 1 day. Latency was longer, and rate of production of virus slower, in primary cultures of the fibroblast and epithelial types, with maximum yields attained a day earlier in the former type of culture. In both types of primary cultures, virus yields even after 2–3 days of infection were 15–25 times lower than one-day yields in the cell line cultures. Table 2 shows that the pattern of reaction to infection with virus was the same when multiplicities ranging from 4 to 0·04 plaque-forming units per cell were used. Macrophage cultures failed to support virus proliferation at all three multiplicities. Forty-five-hour yields in lung cultures were 7–30 times as high as those in primary kidney cultures, while the yield of cell line cultures inoculated at a multiplicity of 0·04 plaque-forming units per cell was 2–4 times that of lung cultures inoculated at a hundred-fold higher multiplicity.

These differences in the rate and yield of infectious virus production may be a reflexion of one or more factors involved in virus-cell interactions. These include efficiency of adsorption and penetration, of initiation of infection leading to the formation of viral sub-units, and of the assembly of these units into mature viral particles. The absence or presence in varying amounts of aberrant by-products of viral infection, including those of the nature of interferon, may also play a part. Preliminary experiments indicate that there are variations in the efficiency of virus adsorption. These, however, cannot account for the much more marked differences in plaquing efficiency of the virus in the different cell systems. Details of these and other experiments designed to explore the possibilities mentioned here will be published elsewhere.

PSYCHIATRY

'Dream Time' in Hallucinating and Non-hallucinating Schizophrenic Patients

Observers of human behaviour have long commented on the similarities between the hallucinations of madness and the normal, universal hallucinations of dreaming[1]. Some have postulated that the two kinds of hallucination

share a common mechanism and that a derangement of this mechanism occurs in psychosis. If this were so, one might expect derangement of the mechanism to be present in sleep as well as waking, with a resultant alteration of the amount of dreaming; unfortunately, present theories (whether physiological[2] or psychological[3]) do not explicitly predict the direction of such changes. However, the discoveries of Aserinsky, Dement and Kleitman now permit an empirical approach to this problem. These investigators have demonstrated that in both normal and schizophrenic subjects the low-voltage fast electroencephalogram (EEG) pattern of sleep accompanied by rapid eye movements (REM) is highly correlated with the subjective experience commonly described as dreaming[4]. The present study represents an application of their methods to the estimation of dream time in hallucinating and non-hallucinating schizophrenic subjects.

Table 1. Dream Time in Hallucinating and Non-hallucinating Patients

Values for each subject are means for the data of five nights, except for patient 4 for whom data of only four nights were available. Per cent values are the means of the nightly percentages. Dream time per cent = (dream time/sleep time) × 100; REM time per cent = (sum pages with one or more rapid eye movements/sum pages sleep) × 100

Group	Patient No.	Sex	Age (yr.)	Sleep time (min)	Dream time (min)	Dream time (%)	REM time (%)
Hallucinators	1*	F	23	387	59	15·4	9·5
	2*	M	35	218	41	19·2	16·7
	3	M	20	370	67	17·9	12·4
	4	M	22	397	94	23·7	18·4
	5	M	25	381	75	19·4	13·6
	6*	F	26	383	96	25·1	12·9
	7	M	40	469	163	34·7	14·7
Mean			**27·1**	**372**	**85**	**22·2**	**14·0**
Non-hallucinators	8	F	26	370	79	20·8	12·8
	9	M	21	436	126	29·0	18·5
	10*	F	25	402	87	21·8	13·3
	11	M	22	348	64	18·4	8·7
Mean			**23·6**	**389**	**89**	**22·5**	**13·3**

* For five consecutive days, patient No. 1 received 10 mg of trifluoperazine, No. 2 received 200 mg thioridizine and No. 10 received 20 mg of trifluoperazine and 5 mg of procyclidine. In each case, medication was discontinued two days prior to recording. For thirteen consecutive days patient No. 6 received 20 mg of trifluoperazine and 5 mg of procyclidine, which were discontinued four days prior to recording.

Seven hallucinating and four non-hallucinating patients were examined. None of the patients had a history or findings suggestive of organic brain disease. All hallucinating subjects were experiencing auditory hallucinations, and three of them (Table 1, Nos. 1, 2 and 6) reported visual hallucinations as well. Four subjects were receiving tranquillizing drugs which were stopped at least two days prior to their first recording (Table 1); none of the other patients received medication during the preceding 30 days. Subjects were permitted to retire at their usual bedtimes but, in accordance with the ward schedule, all were awakened at 6·00–6·30 a.m. We usually examined two patients each night and attempted to obtain five consecutive all-night recordings for each subject. Electrode attachments for recording vertical and horizontal REM and a unipolar left occipital EEG were led to an Offner type *T* electroencephalograph which was run continuously at 15 mm/sec.

The usual scoring scheme[5] for estimating dream time from such records takes as the onset of dreaming the emergence of low-voltage fast EEG without sleep spindles or *K*-complexes (Stage 1 of Dement[6], *B*-stage of Loomis[7]), which typically precedes the first rapid eye movement. Correspondingly, the end of the dream period is taken as the end of the emergent Stage 1 activity and the onset of Stage 2 (spindles and *K*-complexes on a low to medium voltage background). Inspection of the records we obtained soon revealed serious obstacles to the use of this scoring system. The EEG tracings of some hallucinating and non-hallucinating patients showed patterns intermediate between the more clear-cut stages found in normal subjects. In these cases there appeared (usually at the end of REM periods) relatively long intervals of low-voltage fast EEG in which eye movements were absent but which resembled Stage 1 except for occasional bursts of α, spindles or *K*-complexes; the spindle bursts elsewhere were less abundant, shorter in duration and of lower amplitude than usual. In addition, the definite REM periods seemed more often interrupted by body movements and by Stage 2 EEG; two patients (hallucinators) showed frequent occurrences of spindles and eye movements within the same 20-sec epoch. These apparently unusual patterns are being studied further. Due to the difficulties they presented in classifying EEG, we adopted the following system for estimating time spent dreaming: each 20-sec interval (one page of record) was scored for the presence of REM, spindles and *K*-complexes. Dream time was taken as the number of pages from first to last REM (inclusive) minus any pages on which a spindle or *K*-complex appeared in the absence of REM.

Table 1 gives results for sleep time, dream time and two related measures for the 7 hallucinating and 4 non-hallucinating subjects. The mean values for the two groups are quite similar and none of the differences, as evaluated by the Mann-Whitney *U* test[8], approaches the 0·05 level of statistical significance (two-tailed). Dream time and per cent dreaming are based on eye-movement and EEG criteria combined, as was indicated above. When eye-movement activity is considered separately (REM time per cent) we again find similar values in the two groups.

Thus, our findings fail to support the hypothesis of a difference in dream time between hallucinating and non-hallucinating schizophrenic patients. There are two reasons for suggesting caution in interpreting these results: first, one can never be certain that a patient who denies hallucinations is not in fact experiencing them; secondly, the drugs administered to four of the subjects shortly before participation in the study may have acted to obscure any true difference. Work is now being carried out which controls these factors more adequately[9].

We thank Dr. W. Overholser, then superintendent of Saint Elizabeths Hospital, and Dr. Mary V. McIndoo, chief of psychiatry at D.C. General Hospital at the time these examinations were carried out, for their co-operation. We also thank Dr. J. G. Lofft and Dr. W. Dobbs of Saint Elizabeths Hospital for recommending patients for examination.

FORTHCOMING EVENTS

Monday, September 16—Tuesday, September 17

INSTITUTE OF PHYSICS AND PHYSICAL SOCIETY, MATERIALS AND TESTING GROUP (at the University of Bristol)—Conference on "Some Aspects of Surface Behaviour".

Wednesday, September 18—Friday, September 20

SOCIETY OF CHEMICAL INDUSTRY, FOOD GROUP (at the School of Pharmacy, Brunswick Square, London, W.C.1), at 9.30 a.m. daily—Symposium on "Food Technology in Europe".

Thursday, September 19

BRITISH INTERPLANETARY SOCIETY (at University College, Gower Street, London, W.C.1), from 10 a.m. to 5 p.m.—Symposium on "Satellite Meteorology".

INSTITUTION OF CHEMICAL ENGINEERS (at the Royal Aeronautical Society, Hamilton Place, London, W.1), at 5 p.m.—Mr. T. J. Williams: "Progress in Chemical Process Control in America: Computers, Instrumentation, and Applications".

INSTITUTION OF MINING AND METALLURGY (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Friday, September 20

BRITISH ASSOCIATION OF CHEMISTS (at the Royal Society of Medicine, Wimpole Street, London, W.1), at 6.30 p.m.—Mr. Henry T. F. Rhodes: "The Progress of Forensic Science" (Hinchley Memorial Lecture).

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

HEAD (with good academic qualifications, teaching and/or industrial experience, and able to organize research) OF THE ELECTRICAL ENGINEERING DEPARTMENT—Clerk to the Governors, Woolwich Polytechnic, London, S.E.18 (September 19).

RESEARCH ASSISTANT IN APPLIED PHYSICS; and a RESEARCH ASSISTANT IN METALLURGY—The Vice-Principal, Lanchester College of Technology, Priory Street, Coventry (September 20).

LECTURER IN PATHOLOGY at Makerere University College, East Africa—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (September 25).

LECTURER (with a degree or diploma in the social, biological or physical sciences or technology, and some research and/or teaching experience relevant to ergonomics and/or cybernetics) IN THE DEPARTMENT OF ERGONOMICS AND CYBERNETICS—The Academic Registrar, Loughborough College of Technology, Loughborough, Leicestershire (September 30).

LECTURER (with some experience of hospital laboratory work, and preferably some teaching experience) IN THE DEPARTMENT OF CLINICAL CHEMISTRY—The Secretary, The University, Edinburgh (September 30).

LECTURER (with a special interest in electron theory of alloys and related topics) IN THE DEPARTMENT OF METALLURGY—The Registrar, The University, Liverpool, quoting Ref. CV.406 (September 30).

PROFESSOR OF MATHEMATICS (either Pure or Applied)—The Registrar, The University, Leeds 2 (September 30).

SENIOR LECTURER IN GEOGRAPHY at Victoria University of Wellington, New Zealand—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, September 30).

ASSISTANT LECTURER IN SOCIOLOGY IN THE SCHOOL OF SOCIAL STUDIES—The Registrar, University of Essex, Wivenhoe Park, Colchester, Essex (October 1).

CHAIR OF ENGINEERING SCIENCE—The Registrar and Secretary, University of Durham, 38 North Bailey, Durham (October 7).

TECHNICAL ASSISTANT (with experience in fitting and turning, and preferably a knowledge of instrument making) IN THE DEPARTMENT OF PHYSICS, Rhodes University, Grahamstown, South Africa—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, October 10).

LECTURER IN PATHOLOGY—The Secretary, The Queen's University, Belfast, Northern Ireland (October 11).

LECTURER or ASSISTANT LECTURER (medically or non-medically or veterinary qualified candidate) IN THE DEPARTMENT OF HISTOLOGY—The Registrar, The University, Liverpool, quoting Ref. No. CV/403/N (October 11).

CHAIR OF PHYSICS—The Secretary, University of Lancaster, Lancaster (October 12).

CHAIR OF MATHEMATICAL STATISTICS—The Registrar, University of Sussex, Stanmer House, Stanmer, Brighton, Sussex (October 15).

LECTURER or ASSISTANT LECTURER IN PHYSIOLOGY at the University of Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (October 15).

LECTURER or ASSISTANT LECTURER IN GEOGRAPHY; and a LECTURER or ASSISTANT LECTURER IN THE SUB-DEPARTMENT OF THE HISTORY OF SCIENCE IN THE DEPARTMENT OF PHYSICS, University of Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (October 15).

LECTURER or ASSISTANT LECTURER IN PLANT BREEDING AND GENETICS at the University of Ife, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (October 15).

B.I.P. RESEARCH SCHOLAR (with a good degree, including chemistry), to work under the direction of Dr. P. H. Plesch, on problems related to cationic polymerization—The Registrar, The University, Keele, Staffordshire (October 21).

RESEARCH OFFICER (with a Ph.D. degree or postgraduate research experience of equivalent standard and duration, supported by satisfactory evidence of research ability, and preferably experience in reaction kinetics, surface or solid-state chemistry, and/or high vacuum technique) IN THE DIVISION OF COAL RESEARCH, Commonwealth Scientific and Industrial Research Organization, North Ryde, New South Wales, Australia, to undertake fundamental research on the mechanism of catalysis of the reactions of carbon with oxidizing gases—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 480/428 (October 26).

CHAIR OF MORAL PHILOSOPHY—Secretary to the Curators of Patronage, University of Edinburgh, Old College, South Bridge, Edinburgh 8 (October 31).

CHAIR OF PHYSICAL GEOGRAPHY—The Registrar, University College of Wales, Aberystwyth (October 31).

DIRECTOR (with high academic qualifications and extensive experience of research and of the administration of research) OF THE TEA RESEARCH INSTITUTE OF CEYLON—The Chairman of the Tea Research Institute of Ceylon, "Lynwood", 50 Edinburgh Crescent, Colombo, Ceylon; and Dr. F. R. Tubbs, C.B.E., Director, East Malling Research Station, East Malling, Maidstone, Kent (November 11).

GENETICIST (with a good honours degree and a background of Drosophila genetics and biochemistry)—The Secretary, Poultry Research Centre, Agricultural Research Council, King's Buildings, West Mains Road, Edinburgh 9.

LECTURER (well-qualified physicist, with suitable research, industrial or teaching experience, and prepared to join in the development in teaching and research taking place in the Physics Department) IN PHYSICS—The Academic Registrar, Brunel College, Woodlands Avenue, Acton, London, W.3.

PART-TIME RESEARCH ASSISTANT (with an honours degree in botany) IN THE BIOLOGY DEPARTMENT, for an investigation of the anatomy of fruits and seeds—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W.8.

POST-DOCTORAL RESEARCH ASSISTANT (with a Ph.D. in physics or physical metallurgy), to work on a three-year D.S.I.R. sponsored project: superconducting properties of lead–bismuth alloys—Drs. R. L. Bell and H. W. King, Metallurgy Department, Imperial College of Science and Technology, London, S.W.7.

PRINCIPAL LECTURER (graduate of a British university or equivalent qualifications, and preferably experience in teaching heavy-current electrical engineering subjects) IN THE DEPARTMENT OF ELECTRICAL ENGINEERING—The Academic Registrar, Loughborough College of Technology, Loughborough, Leicestershire.

RESEARCH ASSISTANT (graduate with biological qualifications) IN THE DEPARTMENT OF EXPERIMENTAL PATHOLOGY AND CANCER RESEARCH, for work on immunological investigations with emphasis on fluorescence microscopy—Dr. J. O. Laws, Department of Experimental Pathology and Cancer Research, School of Medicine, The University, Leeds 2.

RESEARCH ASSISTANT, to work on turbine blade vibration—Head of the Department of Mechanical Engineering, Battersea College of Technology, London, S.W.11.

SENIOR TECHNICIAN (with considerable experience in a botanical laboratory and in technical photography including photomicrography) IN THE DEPARTMENT OF CRYPTOGAMIC BOTANY—Prof. J. Colhoun, Department of Cryptogamic Botany, University of Manchester, Manchester 13.

TECHNICIAN (recent graduate) IN THE UNIT OF EXPERIMENTAL ECOLOGY, DEPARTMENT OF BOTANY, to assist in nutritional and climatic studies—The Bursar (B.71), The University, Sheffield 10.

For more than 100 years this town has led the world in the manufacture of fine optics. This, together with the famous University, has been the main occupation of the town ever since 1846 when Carl Zeiss and Ernst Abbé opened their first workshop here, even to the extent of establishing a special glassworks to ensure adequate control of quality. During these years son has followed his father's craft, learned its intricacies from childhood, and absorbed the tradition of a century. Nowhere else in the world is there such an accumulation of knowledge on this subject.

The finest microscopes in the world come from HERE

The entire range of research, routine, and specialist microscopes manufactured at Jena have such high definition and image brightness and such a wide field of view that the operator is virtually taken into another world, the world of the specimen. This effect, which removes much of the strain from microscopy, is obtainable with no other instrument.

APPOINTMENTS VACANT

UNIVERSITY OF EDINBURGH
RESEARCH FELLOWSHIP IN SEISMOLOGY

Applications are invited for a D.S.I.R. Research Fellowship in Seismology, tenable in the Department of Astronomy of the University of Edinburgh. Applicants should be prepared to undertake field and laboratory studies of seismic waves and to relate their observations to earth structure and tectonics. Advanced equipment is available for recording on magnetic tape and for high-speed playback in analogue or digital form. Qualifications must include Ph.D. or equivalent postgraduate experience in experimental geophysics. Experience in the maintenance or development of electronic equipment is desirable but not essential. The Fellowship will initially be available until April 1, 1965, with good prospects of extension. Salary in the range £900 to £2,000 per annum, according to qualifications and experience.

Applications, including the names of two referees, should be sent to the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh, by September 30, 1963.

PILKINGTON BROTHERS LIMITED
Glass Manufacturers, require a

PHYSICIST

at their Research Laboratories to carry out basic research work involving model studies of viscous and non-viscous flow and heat transfer problems.

A good honours degree in physics is essential, with some experience of university or industrial research.

The position is in a salary range which can rise to £2,000 per annum.

Please quote RES./J3 in applying to L. P. Laidlaw, Group Staff Department,

PILKINGTON BROTHERS LIMITED,
Grove Street, St. Helens, Lancashire.

UNIVERSITY OF MANCHESTER

Applications are invited for two posts of Lecturer in Radio-astronomy in the Department of Physics of the Faculty of Science. The successful applicants will be expected to pursue research at the Nuffield Radio-Astronomy Laboratories, Jodrell Bank, where the Mark I 250 ft. Radio Telescope is in operation and the Mark II instrument is under construction. A specialized knowledge of radio-astronomy is not essential and applicants with interests or experience in electronics, astronomy or astro-physics are encouraged to apply. Salary scale from £1,250 to £2,150 per annum; initial salary according to qualifications and experience. Duties to commence as soon as possible. Membership of the F.S.S.U. and Children's Allowance Scheme.

Applications should be sent not later than September 30, 1963, to the Registrar, the University, Manchester, 13, from whom further particulars and forms of application may be obtained.

AGRICULTURAL RESEARCH COUNCIL

Geneticist with background of Drosophila genetics and biochemistry required for the staff of the Poultry Research Centre, Edinburgh. Good honours degree essential. Appointment as Scientific Officer in scale £791 to £1,309 according to experience. F.S.S.U. Applications, with names of three referees, to Secretary, Poultry Research Centre, King's Buildings, West Mains Road, Edinburgh 9.

COMMONWEALTH OF AUSTRALIA

COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION

DIVISION OF FISHERIES AND OCEANOGRAPHY

BIOLOGIST

Applications are invited for appointment to a position of Biologist to be stationed at the Organization's Regional Laboratory in Perth, Western Australia.

The Division is engaged in a programme of study of populations of sperm whales whilst continuing to make observations on humpback whales. The appointee will be expected to assume responsibility for these programmes with a view to making assessment of sperm whales and maintaining watch on the condition of the stocks of humpback whales. The applicant should be able to carry out studies into the biology of whales and to perform the computations required for stock assessments.

Applicants should preferably possess a Ph.D. degree in biology or have had postgraduate research experience of equivalent standard and duration supported by satisfactory evidence of research ability. Applicants should also have had training in modern methods of population research.

Salary: Dependent upon qualifications and experience within the ranges:
£A1,674 to £2,511 per annum (but not less than £A1,979 per annum) or
£A2,655 to £3,015 per annum.

Promotion within C.S.I.R.O. is by merit and may go beyond the upper limit of the scale within which the original appointment is made.

By mutual arrangement the appointment may be for an indefinite period or for a fixed term of three years.

Fares paid for the appointee and his dependent family and return fares to country of origin will be paid for an appointee who accepts appointment for a fixed term. Further particulars supplied on application to:

Mr. P. F. Butler, Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2,

to whom applications (quoting Appointment No. 320/274) should be addressed by October 12, 1963.

Plant Breeding Assistant

There is a vacancy in the Horticulture Section of the Unilever Research Laboratory, Colworth House, for an assistant to the Plant Breeder to work on the production of new varieties of vegetables for processing. Applicants should possess an ordinary degree, or equivalent, in Botany, Agriculture or similar subjects, with some knowledge of genetics.

The Laboratory (total staff 750) offers attractive working conditions, and there are good prospects for advancement.

Please write for an application form to:
THE STAFF OFFICER (REF: FRR 240A),
UNILEVER RESEARCH LABORATORY,
COLWORTH HOUSE, SHARNBROOK, BEDFORD.

UNILEVER RESEARCH

MANCHESTER COLLEGE OF SCIENCE AND TECHNOLOGY
(Faculty of Technology in the University of Manchester)

Applications are invited for a temporary post of Experimental Officer in the Department of Chemistry to carry out research and development work on the controlled oxidation of aromatic compounds and of more complex materials. The initial tenure will be for two years and there is the possibility that a suitable candidate would be assimilated into the permanent staff of the department in due course. Candidates should have distinct skill in experimental organic chemistry, and a sound knowledge of chemical theory. Salary range, etc., £880 by £40 to £1,200 per annum. Family allowances. Superannuation Scheme.

Conditions of appointment and forms of application may be obtained from the Registrar, The Manchester College of Science and Technology, Sackville Street, Manchester 1, to whom applications must be returned as soon as possible.

CITY OF LIVERPOOL EDUCATION COMMITTEE
COLLEGE OF TECHNOLOGY
Principal: S. A. J. Parsons, B.Sc.(Econ.), M.I.Mech.E., M.I.Prod.E., M.B.I.M.

Applications are invited for the following appointments. (1) Lecturer in Mathematics. Applicants should be prepared to teach to graduate level. They should have teaching and industrial or research experience, and be prepared to undertake research. (2) Lecturer in Physics. Applicants should be suitably qualified, able to teach up to degree and Diploma in Technology level and be prepared to undertake research. A special interest in Acoustics is desirable. Teaching and industrial or research experience is essential. Salaries: Lecturer: £1,670 by £45 to £1,895 per annum.

Application forms (returnable by September 23, 1963) and further particulars from Director of Education, 14 Sir Thomas Street, Liverpool, 1.

THOMAS ALKER,
Town Clerk.

AUSTRALIA

COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION

DIVISION OF ANIMAL HEALTH

VETERINARY PARASITOLOGIST

Applications are invited for appointment to a position of a Veterinary Parasitologist with the Organization's McMaster Animal Health Laboratory, situated in the grounds of the University of Sydney, with which a close association is maintained.

The appointee will be required to participate in specific aspects of the programme of research concerned with the epidemiology and control of helminth infections of sheep.

Applicants should possess a degree in Veterinary Science, or its equivalent, together with a Ph.D. degree or research training of an equivalent standard and duration, and must present satisfactory evidence of postgraduate experience in a relevant field of parasitology.

SALARY : Dependent upon qualifications and experience within the range :

£A1,674 to £A2,511 per annum (but not less than £A1,979 per annum).

Salary for a woman will be £A188 per annum less than corresponding rates for men.

Promotion within C.S.I.R.O. is by merit and may go beyond the upper limit of the scale within which the original appointment is made.

Fares paid for the appointee and his dependent family. Further particulars supplied on application to :

Mr. P. F. Butler, Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, W.C.2, London, to whom applications (quoting Appointment No. 202/200) should be addressed by October 12, 1963.

Soil Scientist
for research opportunity

COMINCO invites applications for a responsible position in its soil-fertilizer chemistry research programme.

Candidates should hold or soon obtain a Ph.D. degree in either Soil Chemistry, Soil Science, or in Soil Fertility and Plant Nutrition. Research experience in the fields of minor element soil-chemistry or minor elements in plant nutrition is desirable. Duties include developing an active research programme concerned with minor fertilizers; preparation of reports and publications; and maintaining liaison with external research organizations.

Interviews with qualifying applicants will be arranged

Please address inquiries to :

T. McEwan, Personnel Division,
The Consolidated Mining and Smelting Company of Canada Ltd.
Trail, B.C., Canada

THE UNIVERSITY OF LEEDS: SENIOR Technologist required in Medical Research Unit. Must have sound training and experience in electron microscopy (RCA, EMU 3, and Philips EM 100 available) and ultramicrotomy. Possession of science degree or diploma desirable but not essential. Salary between £900 and £1,650 per annum according to training and experience.—Applications and inquiries to Professor C. E. Lumsden, Department of Pathology, School of Medicine, Leeds, 2, not later than September 28.

HISTOLOGY. STUDENT OR JUNIOR Technician required at Toxicology Research Unit, Medical Research Council Laboratories, Woodmansterne Road, Carshalton, Surrey.—Apply, with particulars of education and experience, to the Director.

THE QUEEN'S UNIVERSITY OF BELFAST

DEPARTMENT OF BOTANY

Applications are invited for the post of Research Assistant in the Department of Botany, to commence October 1, 1963. The salary, depending on qualifications and experience, will be in the range £450 to £525. Applicants should be honours graduates in botany or biochemistry and should be interested in working towards a higher degree.

Applications, giving the name and address of a person to whom reference can be made, should be submitted to Professor Carr, Department of Botany, David Keir Building, Stranmillis Road, Belfast, 9, by September 21, 1963.

HORTICULTURE GRADUATES

required by

AN FORAS TALUNTAIS (The Agricultural Institute) for its Horticulture Division. Level of entry to Research Staff depending on qualifications and experience. ESSENTIAL—Honours Degree in Horticulture or equivalent. Marriage and children's allowances. Superannuation Scheme including F.S.S.U. arrangement. Applications also considered from 1963 Degree candidates.

Further particulars and application forms from Director, An Foras Taluntais, 33 Merrion Road, Dublin 4. Latest date for receipt of completed form—October 10, 1963.

BRISTOL COLLEGE OF SCIENCE AND TECHNOLOGY
ASHLEY DOWN, BRISTOL, 7

Department of Physics

The Governors invite applications for the post of :

READER IN SOLID STATE PHYSICS

Applicants should have a good honours degree in physics and appropriate research experience.

The Reader will be expected to play a leading part in the development of the research of the Department, and to pursue actively his own research in some aspect of solid state physics.

Salary (under review) within the range £2,250 to £2,700 per annum.

Please quote reference CST 63/47 (re-advertisement).

ALSO

PRINCIPAL LECTURER IN THE DEPARTMENT OF PHYSICS

Applicants should possess an Honours Degree in Physics or equivalent qualification, appropriate teaching and research experience and administrative ability. Industrial experience would be an advantage.

Salary within the range £2,150 to £2,375 per annum.

Please quote reference CST 63/67.

Further particulars of both posts and application forms from the Secretary and Registrar.

UNIVERSITY OF SYDNEY

TEACHING FELLOWSHIP IN ANIMAL NUTRITION

Applications are invited for the position of Teaching Fellow in Animal Nutrition in the Department of Animal Husbandry. Candidates should be graduates in Agricultural or Rural Science, Veterinary Science or Science. The successful applicant will be required to assist with practical work and lectures in Animal Nutrition and will be encouraged to register for a higher degree. Salary for a Teaching Fellow is within the range £A1,295 by £A60 to £A1,535 per annum, plus cost of living adjustments (at present £A10 per annum). The appointment will terminate on December 31, 1964, in the first instance but may be renewed on an annual basis. Salary will commence from the date of arrival in Sydney.

Applications giving details of qualifications and experience and names of two referees, should be forwarded to reach the Registrar, University of Sydney, Sydney, New South Wales, Australia (from whom further information may be obtained) not later than **October 28, 1963.** In addition, overseas candidates are requested to forward two copies of the application to the Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1.

DIRECTOR OF ANIMAL NUTRITION

- This is a new appointment involving, amongst other responsibilities, the extension of existing facilities so as to provide a national farm advisory service appropriate to the Group's activities in animal feedingstuffs, together with the formulation of animal feeds, the co-ordination of feeding trials and nutritional research.
Applicants should be aged 40–50 and have obtained a position of eminence in the field of animal nutrition, coupled with practical administrative experience at a high level.
The appointment will involve building up an organization, with appropriate scientific backing, to provide the services required; the successful applicant will require considerable energy and determination, as well as the ability to work well with colleagues, to select staff, and to build and lead his own team.
This is a senior position in a large organization; an appropriate salary is envisaged and the appointment is pensionable. The appointment will be based in London or the South of England, but considerable travelling is required and a car will be provided.
- *Write briefly and in strict confidence, quoting Ref.* 14Q/63, *to:*

The Group Staff Manager,

Ranks Hovis McDougall Limited,

53, Eastcheap, London, E.C.3

The British Food Manufacturing Industries Research Association

has the following vacancies for Scientists of graduate standing:

PLANT BIOCHEMIST or BOTANIST

to undertake investigations into the fundamental and technological causes of some defects arising in fruit and vegetable products.

BACTERIOLOGIST

to work on the microbiology of bacon, with particular reference to the microbiological aspects of prepackaging in vacuum film wraps.

Both posts carry Life Assurance and Superannuation benefits. The salary will be commensurate with age and experience. Applications should be sent to the Director of Research, The British Food Manufacturing Industries Research Association, Randalls Road, Leatherhead, Surrey.

THE HYDRO-ELECTRIC COMMISSION, TASMANIA

GEOLOGIST **Salary £A1,474 to £A2,496 per annum.**

Duties will include regional mapping, logging and interpretation of drill cores and detailed investigations of dam sites, conduit routes, etc.

GEOPHYSICIST **Salary £A1,474 to £A2,496 per annum.**

Required to carry out geophysical surveys in connection with geological investigations and hydro-electric construction.

Applicants for either position must hold a degree in Science or Engineering with Geology as a major subject.

Headquarters—Hobart.

Travelling expenses payable and general information from the Agent General for Tasmania, 457 Strand, London, W.C.2, to whom applications, in duplicate, supported by copies of references or names of referees, should be addressed.

EAST AFRICAN COMMON SERVICES ORGANIZATION

Research Officer (Entomologist) required to plan and carry out research on the biology of malaria carrying mosquitoes in East Africa, and to direct field and laboratory work of an established entomological research team. Candidates must possess an honours degree in biology, with appropriate postgraduate experience, and be nationals of and permanently resident in Great Britain or the Republic of Ireland. Appointment on contract for one tour of two years with gratuity (taxable) of 25 per cent of emoluments on satisfactory completion of contract. Salary within the scale £2,172 to £2,808 a year. Free return passages for officer, wife and up to four dependent children. Education allowances. Mid-tour passages for children being educated in the United Kingdom. Furnished quarters available at low rental. Approximately four months home leave on full salary on satisfactory completion of contract. Local leave of sixteen days a tour also allowed.

Application forms from Director of Recruitment, Eland House, Stag Place, Victoria, London, S.W.1. (Please quote RC.318/145/02 and state full name.)

AUSTRALIA

UNIVERSITY OF NEW SOUTH WALES

invites applications for appointment to the positions of

LECTURER/SENIOR LECTURER
DEPARTMENT OF BOTANY
SCHOOL OF BIOLOGICAL SCIENCES

Salary: Lecturer, £A1,905 range £A2,605 per annum. Senior Lecturer, £A2,755 range £A3,255 per annum. Commencing salary according to qualifications and experience. Applicants must hold an honours degree with research qualifications in botany or a related field of biology, equivalent to the Ph.D. Qualifications in genetics (including cyto-genetics, biometrical genetics or fungal genetics) would be advantageous for one position, whilst experience in plant physiology (including growth analysis) and/or biochemistry would be desirable for the other position. The Department of Botany under Professor H. N. Barber, F.R.S., is housed in a new building together with the Departments of Biochemistry, Microbiology and Zoology. The School is equipped with advanced biochemical apparatus, glass houses, constant environment facilities, and field stations. The successful applicants will lecture at both undergraduate and postgraduate level and there will be opportunities for research.

Details of conditions of appointment, including superannuation, study leave, housing scheme and travel arrangements, may be obtained from the Agent-General for New South Wales, 56-57 Strand, London, W.C.2, with whom four copies of applications including the names of two referees should be lodged before October 30, 1963. A copy of the application should be forwarded by airmail to the Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, N.S.W., to reach there before the above mentioned date.

BIRKENHEAD EDUCATION COMMITTEE

BIRKENHEAD TECHNICAL COLLEGE

Principal: C. V. Vinten Fenton, M.Sc., A.M.I.Mech.E., A.M.I.E.E.

Applications are invited for the undermentioned full-time teaching staff:

SCIENCE DEPARTMENT

Lecturer in Physical Chemistry.

Assistant Lecturer Grade "A"—Chemistry.

Salaries in accordance with the Burnham Technical Scales, 1961, as amended by the Remuneration of Teachers (F.E.) Order, 1963.

Further particulars and forms of application may be obtained from the undersigned, to whom completed applications should be returned by September 24, 1963.

H. GLYN WILKINSON,
Director of Education.

Education Offices,
63 Hamilton Square, Birkenhead.

KINGSTON UPON HULL EDUCATION COMMITTEE

COLLEGE OF TECHNOLOGY

Principal: Emlyn Jones, M.Sc., F.R.I.C.

Applications are invited for the post of Senior Lecturer in Theory of Machines and Machine Design to commence duty as soon as possible. Applicants must be honours graduates with wide industrial and teaching experience able to undertake research. Salary: Burnham Technical Scale, £1,895 by £55 (4) to £2,115 per annum.

Application forms and further particulars, to be returned within 14 days of the date of this issue, may be obtained from the Chief Education Officer, Guildhall, Kingston upon Hull.

NUCLEAR POWER POLITICS IN BRITAIN

IT is obvious from the figures for expenditure and man-power given in the ninth annual report of the United Kingdom Atomic Energy Authority* that the pre-occupation of the Authority is overwhelmingly with the reactor programme and the research on which any such development must be based. It is scarcely surprising that when the content and scale of Britain's nuclear power programme is being criticized the future position of the Authority should also be the subject of comment. Beyond a reference to the work on two possible reactor systems for the merchant marine field (*Vulcain* and the integral boiling reactor), on which attention was concentrated during the year, and to the probability that in the long term substantial quantities of enriched uranium will be required for the civil nuclear power programme, the report does not attempt to consider the future prospects for nuclear power. However, they were the subject of some discussion in a debate in the House of Lords on July 10, although that debate was largely concerned with the merits of a Government decision regarding a tender for the new Wylfa power station. The competitivity of nuclear power at January 1, 1963, however, is considered in a paper recently published by the Comitato Nazionale Energia Nucleare†, which takes the view that nuclear power is on the threshold of economic competitiveness. It does not accept entirely without question the statement that the advanced gas reactor in the United Kingdom could produce electric power at 0·45*d.*/kWh, since the statement is based on suppositions that are open to challenge. These include the distribution of overheads, design and construction costs over a programme calling for sufficient such stations to supply at least 6,000 MWh to cover the Central Electricity Generating Board's requirements by 1968.

By 1970, however, at least 10 per cent of Britain's electric power capacity will be represented by nuclear plant, at a cost for magnox gas-graphite reactors of 0·6*d.*/kWh, and lower still for the advanced gas reactor. It was argued by Lord Aldington in the House of Lords that, if the right methods of calculation of costs were used, nuclear power would prove broadly comparable with the best sources of conventional power during 1965–66; if the same output was programmed in future from each design of nuclear power station as for each design of conventional plant, the costs of nuclear power would prove substantially lower. Further, failure to calculate costs correctly had led to false ideas as to the competitiveness of nuclear power, which had discouraged the building of such stations. He believed that the earlier hopes held out for nuclear power were fully justified, but national policy on nuclear power should be guided throughout by a firm belief in its competitiveness and in its economics. It was not the technical efficiency of nuclear power plant or the capability of its designers or anything inherent in nuclear energy itself that appeared to keep its cost above those of conventional power.

The debate had opened on a motion of Lord Coleraine asking for a committee of enquiry into the present arrangements and prospects of the nuclear energy industry. He had been particularly disturbed at the break-up of teams of skilled designers and others under the present arrangements, and in this he was fully supported by Lord Aldington and Lord Stonham. Lord Aldington had also challenged the acceptance of a depreciation period of twenty years for nuclear plants as too pessimistic; although it was possibly justified in 1955, to-day it was out of date, and one of twenty-five or thirty years should be substituted. Lord Mills, however, pointed out that the Powell Committee, on which the Atomic Energy Authority, the Central Electricity Generating Board, the Ministry of Power, the Treasury and the Board of Trade were represented, was already examining the position. In view, too, of the comments of the Select Committee on Nationalized Industries on the electricity supply industry in a report published last May, he thought that all the facts were sufficiently well known, and that a radical review of the commercial thinking of the industry had already been put in train.

In replying for the Government on the debate, the First Lord of the Admiralty, Lord Carrington, began by sketching briefly the history of nuclear power programmes since the first orders for such power stations were placed in 1956. In March 1957, it was decided to adopt a much expanded construction programme amounting to the installation by the end of 1965 of 5,000–6,000 MW of nuclear generating capacity, in view of an expected serious shortage of fuels. By October of that year, however, it was decided to stretch the programme over a longer period and to reduce the rate of installations. The four industrial Consortia formed in 1954 also obtained two overseas contracts, in Italy and in Japan. When the strain on Britain's coal supplies had eased and prospects for oil supplies improved in October 1960, the Government again revised the programme and it was decided to order nuclear power stations at the rate of about one a year. In this situation, and in the absence of further export orders, the Consortia re-grouped themselves into three organizations.

Lord Carrington emphasized that the nuclear power policy was part of the wider energy policy, and pointed out that for 1960–68 the programme concentrated on the development of nuclear technology and construction capacity against the needs of many years hence. The scale and pattern of the nuclear programme after 1968 was the subject of a more detailed study of the economic and technical factors and prospects, which was put in hand last year in co-operation with the electricity supply industry and the Atomic Energy Authority. Basic research and development of reactor systems were the responsibility of the Atomic Energy Authority, which had a statutory responsibility to develop nuclear energy. However, neither Lord Carrington nor the Minister for Science, to whom the Authority is responsible, when he spoke later, said anything to remove the current uneasiness as to the continuing magnitude of the Authority's effort or its relation to the civil research and development effort generally. Lord Carrington did, however, point out that the Authority's relations with the Consortia covered more than the present constructional programme, and associated them from the beginning in new designs of reactors developed by the Authority. As to costs, he

* United Kingdom Atomic Energy Authority. Ninth Annual Report for the period 1st April, 1962–31st March, 1963. Pp. ix + 87 + 7 plates. (London: H.M.S.O., 1963.) 6*s.* 6*d* net. (See also p. 1141 of this issue of *Nature*.)

† Competitivity of Nuclear Energy at 1 January, 1963. Pp. 25. (Rome: Comitato Nazionale Energia Nucleare, 1963.)

pointed out that these depended on whether more or less favourable assumptions were adopted regarding various factors, operators of such stations tending to take the more conservative, and organizations responsible for research and development, the more optimistic assumptions.

Lord Carrington vigorously repudiated the suggestion that the Generating Board and not the Government was the arbiter of the nuclear power programme, but he held out no hope of an early decision by the Government which would make a final apportionment of costs between the taxpayer and the consumer in the development of nuclear power. Without public funds, however, it was unlikely that development of nuclear power would have occurred at all. Lord Hailsham affirmed his complete confidence in the future of nuclear power, but fully accepted the need for an enquiry into the economics of nuclear power. He did not disclose, however, the terms of reference of the Powell Committee, but indicated that, broadly speaking, it was designed to reconcile the differences of view which might legitimately be held about the economics of nuclear and of conventional power, and, to some extent, about the economics of particular types of reactor.

Accordingly, Lord Hailsham suggested that judgment on these issues should be postponed until the Powell Committee had reported on the general situation. Dounreay, he admitted, would have a very marked bearing on the economics of nuclear power in the future, both because of the high hopes of the breeder factor in the fast reactor, and also because of the possibility of the reactor burning plutonium. That, however, lay in the future. He also declined at that stage to commit the Government to overriding any decision of the Central Electricity Generating Board affecting the future of the Consortia but agreed that any suitable representation should be considered.

Lord Hailsham was apologetic for his slender contribution, which certainly seemed to emphasize the excessive extent of his responsibilities outside those of science and technology, particularly in view of the rarity of debates on nuclear power in the House of Lords. Concern regarding the future of the Atomic Energy Authority may well be unjustified. The extent of the resources which Britain can commit to this field, however, requires continued appraisal in the light of her whole research and development effort. The Authority's report is not a discouraging document, however; but it is disappointing to find that in such a debate the responsible Minister could neither comment on the report of the Atomic Energy Authority itself nor on the importance of that effort in civil research and development as a whole.

APPROACHES TO ATOMIC PHYSICS

THE Vanuxem Lectures delivered by Prof. C. N. Yang in Princeton University during 1959 have recently formed the basis of a book*, the essential purpose of which is to give an account of the historical development of our ideas of the fundamental constitution of matter for an audience of educated people with an interest in science but not technically expert in the subject. This it does by a lucid description of the most crucial experiments and new conceptions, illustrated by diagrams and photographs. The topics discussed include the discovery of the electron and of the nuclear atom; the development of quantum mechanics; the discovery of the neutron, the mesons and hyperons; and the idea of parity with the demonstration of its non-conservation in weak interactions.

Prof. Yang emphasizes the important part in the progress of discovery played by technical innovation, and the essential contribution made by the interplay between theory and experiment. The work is enriched by a number of quotations from eminent physicists bearing on the main theme.

Such a book, written by a mature and competent authority, is a valuable contribution to the wider dissemination of scientific culture; but it also serves a second purpose scarcely less important. There is a growing tendency in teaching physics to abandon the traditional treatment which roughly follows the historical development of the subject. In the interests of economy of time and simplicity of presentation, it is being replaced by a logical treatment in which the historical sequence is ignored. There is much to be said for such an approach when the aim is to give instruction to students of other disciplines for whom a knowledge of physics is an essential piece of technical equipment; or when the content of an honours course in physics has become so formidable that there are advantages in removing all material which appears not strictly essential. But for those who are going to be serious investigators in physics, such an unhistorical approach sacrifices much of importance, and books like Prof. Yang's do something to restore a balance.

There are two serious deficiencies in a strictly utilitarian and unhistoric syllabus. In the first place, it can lead to graduates who are well instructed and soundly indoctrinated, but who have no acquaintance with the spirit of enquiry and how discoveries are made. Discovery to them appears as a kind of magic, the result of the sudden insight of a man of genius. There is as much to be learned about the nature of discovery from a knowledge of those experiments which failed as from those which succeeded. To stress only the latter gives little insight into the great and exciting human activity which we call research.

It is probable that most university students in physics are shown J. J. Thomson's experiment on the measurement of the ratio of the charge to the mass of the electron; but how many are told of Hertz's earlier experiments of a similar nature, to which Prof. Yang refers, and which failed to show any deflexion so that it was concluded that the cathode-rays are uncharged ? Or of the assumptions made earlier by Schuster which led him to interpret similar experiments as indicating that the cathode-rays are charged atoms ?

A familiarity with the main lines of development of a scientific discipline is not to be seen as a kind of embellishment of knowledge, but as an essential part of a mature understanding. It can be especially important in providing some sense of direction in those difficult decisions which are sometimes involved in deciding general lines of policy for a whole future period of investigation. History, including the history of science, is not 'bunk', even although it never provides ready-made solutions of present problems which allow us to escape the exercise of judgment.

* *Elementary Particles: a Short History of some Discoveries in Atomic Physics. (The Vanuxem Lectures, 1959.)* By Dr. Chen Ning Yang. Pp. 68. (Princeton, N.J.: Princeton Univ. Press; London: Oxford Univ. Press, 1961.) 22*s.* net.

At the present time elementary particle physics presents us with just such difficult decisions. For the sixty years which Prof. Yang brings under review there has been a ceaseless flow of discovery to which Europe has made a unique contribution, and to-day the subject appears to be full of life and vitality. But in the next few years we shall have to decide whether to build a great new accelerator for the technical equipment of Europe in ten or twenty years time. The cost of a proton-synchrotron for an energy of about 300 GeV is in the range of £150 million. Are we justified in committing such large resources when it seems unlikely that we can hope for any early return in the form of practical applications such as those which followed from the advances in nuclear physics which culminated with the discovery of the fission process ? When such a machine comes into operation, in ten or fifteen years time, what will be the state of the subject ? Moreover, in particular, will it still be attracting a large fraction of the most gifted of the youth of the world who devote themselves to science ? Will it perhaps be superseded before it comes into operation through unexpected technological innovations which will allow the production of high-energy beams of protons, in high intensity, at a greatly reduced cost ?

It seems very unlikely that we shall be able to find clear-cut and well-founded answers to all these problems before it is necessary to make a decision. Some scientists are therefore opposed to a new generation of accelerators for Europe, and are willing to accept the consequence that, in this field, Western Europe would decline into an entirely secondary position. It has even been said, if with irony, that the only consequence of Rutherford's discoveries is that the present cost of electricity in Britain is more than it would otherwise have been.

The proponents of such a view would get much benefit from reading Prof. Yang's book. He quotes a passage from the 1930 Faraday Lecture in which Bohr speaks of the new prospects for the whole of physical and chemical science opened up by the discovery of the atomic nucleus. The main fruits of the great developments of nuclear physics in the first half of the twentieth century are not so much the technological triumphs in nuclear energy, but rather that our whole concept of matter has by them been radically transformed so that all our science and technology are infused with the ideas which were born in that epoch.

Our present position is not so clear as in 1912 when the consequences for many sciences of the discovery of the nuclear atom could be enthusiastically discussed, but it is a reasonable speculation in the light of the history of the subject that a great increase in our understanding of Nature will indeed follow from the advances in elementary particle physics in the next two or three decades. The subject is advancing with explosive rapidity; there are many profound questions which we can ask and for which at the moment we see neither the solution nor even a serious approach. But, as Prof. Yang remarks, in discussing recent progress in our new understanding of the remarkable symmetries which Nature displays, "one learns to hope that Nature possesses an order that one may aspire to comprehend". All our history suggests that a great development in our understanding will again in the long run infuse all our thinking, with profound consequences for philosophy and practice.

Confidence that Nature is indeed an ordered and logical system which man can therefore aspire to understand was of crucial importance in the development of modern science. The notion is embodied in the idea of the 'Laws of Nature'—a phrase which gained widespread currency only quite late in the Renaissance and which evidently owes much to theological ideas; as Needham remarks†, "Just as earthly imperial law-givers enacted codes of positive law to be obeyed by men, so also the celestial and supreme rational creative deity has laid down a series of laws which must be obeyed by minerals, crystals, plants, animals and the stars in their courses". Believing the world to be an ordered system, men were encouraged to attempt to unravel it. This was an idea unacceptable to classical Chinese thought, and it is suggested by Needham that its disposition to regard Nature as inscrutable, as too complex to be unravelled is one reason why Chinese science made little headway in a period when Western science was making spectacular advances. In this sense, Chinese thought at this period was too subtle; it was too impressed by the immense complexity of phenomena so that in Needham's phrase, "it was groping after an Einsteinian world-picture without having laid the foundations for a Newtonian one".

Our present belief that there is a great future field of discovery in elementary particle physics, crucial for our decision as to what resources should be devoted to it, is again an expression of our confidence of order in Nature. We know, for example, of four principal forces, gravitational, electro-magnetic, nuclear, and the weak forces responsible for such processes as the β-decay. At the present time they appear entirely unrelated; there is no serious approach to a unified field theory embracing them all. But we are confident that one day the relations between them will be established and that our present ignorance is a guarantee that rich fields of discovery lie ahead.

Or again, the facts about the elementary particles and their excited states or resonances appear at the moment as an empirical body of knowledge and their deeper significance escapes us. But we believe that there must be an underlying order which we can discover, just as was the case with the excited states of atoms. No doubt the order is of a different kind from that which prevails in atomic systems; but our problems ought not to appear more forbidding to us than did the task of unravelling atomic spectra to physicists a hundred years ago.

Against this background, Prof. Yang's remark is particularly interesting. It is remarkable that two of the most subtle and profound contributions to elementary particle physics in the past thirty years, by Yukawa, and by Lee and Yang, respectively, have been made by representatives of oriental cultures who have made themselves masters of Western scientific thought. It shows the great benefits to science which have followed from its international dissemination. This has ensured that the representatives of different cultures, who cannot but be deeply influenced by the particular climate of ideas in which they have been fostered, have been enabled to contribute to its development. And it is a promise for the future when this process will have progressed even further.

Prof. Yang's book serves not only as a valuable contribution to the dissemination of scientific culture but also to emphasize the place of the history of science in our thinking, and we should feel most indebted to him that he found the time to write it.

INTRACELLULAR 'FREE' AMINO-ACIDS

Amino Acid Pools

Distribution, Formation and Function of Free Amino Acids: Proceedings of a Symposium on Free Amino Acids held at the City of Hope Medical Center, Duarte, California, May 1961. Pp. xi+815. Edited by Joseph T. Holden. (Amsterdam, London, New York: Elsevier Publishing Company, 1962.) 120*s*.

IT is now a commonplace of biochemistry that treatment of living cells with boiling water, detergent solutions, alcohols or mild acids in the cold, etc., releases mixtures of free amino-acids from within the cells. Therefore the cells contain amino-acids either in the free state or in some form from which they are readily released in the free state. Such intracellular amino-acids constitute the 'amino-acid pool' of the cell, and pools have now been described in cells ranging from micro-organisms to mammalian, plant and insect tissues. This volume is the first comprehensive collection of data and theories about the nature, distribution, function and variation of amino-acid pools, and presents an expanded account of the proceedings of a symposium held at the City of Hope Medical Center, Duarte, California, in 1961. The volume is edited by J. T. Holden, who was chairman of the Organizing Committee and contributes two major articles on amino-acid pools in micro-organisms. The contributions are set out in detail with many illustrations and accompanied by edited accounts of discussions which followed presentation of the papers at the meeting. Originally the title of the symposium included the term 'free amino-acids', but, since some of the participants doubted whether intracellular amino-acids are truly free, the title of the book has been restricted to the non-committal *Amino Acid Pools*. More than seventy authors contribute to the book, and it would be invidious to single out individuals for specific mention.

Amino-acid pools are relatively easy to study (perhaps deceptively so) and, when quantitative data can be obtained, provide an indication of changes in the metabolic state of the cells. It is essential to establish accurate analytical methods for the extraction, identification and estimation of the amino-acids and to relate the results to the pools in the cells before extraction. When extracts are subjected to examination by paper chromatography, questions arise concerning the nature of unknowns as well as the proper identification of probably knowns. Appropriately, therefore, the volume begins with discussion of analytical techniques, accuracy of identification, production of artefacts and recognition of errors. The first part of the book then contains some thirty papers describing the amino-acids found in pools extracted from plants, micro-organisms, insects and vertebrates and includes six papers on amino-acids of the blood of man and animals in various normal and pathological states and after treatment with drugs. Participants were "encouraged to submit as much chromatographic evidence as they felt was required to document their conclusions". The result is that there are many pages of photographs of chromatograms (a rough count gives 900) which add more to the weight (nearly 4 lb.) of the book than to its scientific value. There is a mass of factual material in these 500 pages which provides a fund of information for anyone contemplating this type of investigation. The particular problems arising from extraction of specific tissues provide many valuable contributions to the methodology of pool investigations.

The second part of the volume contains nineteen contributions on dynamic aspects of amino-acid pools and sets out more fundamental attempts to elucidate the properties and functions of internal free amino-acids. Amino-acid pools can accumulate as a result of endosynthesis or transport of preformed amino-acids from the external medium, and both phenomena raise problems of membrane permeability and transport processes. Various theories of membrane passage are discussed by a number of speakers and the nature, localization and metabolic character of the pool debated. The relationship of free amino-acids to protein metabolism is clearly of importance, and the last group of papers in the symposium deals with protein turnover and its control, the role of free amino-acids as obligatory intermediates in protein synthesis, and the metabolic significance of lipo-amino-acid complexes. The book is completed by a report of a round-table discussion on the state of the intracellular amino-acids.

Protein synthesis occurs much more efficiently in cells than in test-tubes because the cell interior is a highly controlled and integrated metabolic system. The free amino-acid pool provides a delicate measure of the balance of the metabolic processes forming this system and its study should throw much light on cell physiology. This symposium is invaluable for anyone entering the field of amino-acid metabolism in any living tissue and provides, within the compass of one volume, an assembly of information nowhere else available. E. F. Gale

CARBOHYDRATE CHEMISTRY AND BIOCHEMISTRY

Advances in Carbohydrate Chemistry

Vol. 17. Edited by Melville L. Wolfrom. Pp. xi+503. (New York and London: Academic Press, 1962.) 114*s*. 6*d*.

VOLUME 17 of this now venerable series contains rather fewer, but on average longer, articles than its predecessors. There are reviews of higher carbon sugars (J. M. Webber), sugars of the cardiac glycosides (T. Reichstein and E. Weiss), oligosaccharides (R. W. Bailey and J. B. Pridham), platinum-catalysed oxidations (K. Heyns and H. Paulsen), dicarbonyl carbohydrates (O. Theander), purine nucleosides (J. A. Montgomery and H. J. Thomas), and enzymatic synthesis and degradation of starch and glycogen (D. J. Manners). Most of the articles bring earlier reviews up to date, as well as covering new ground; the chapter on oligosaccharides provides the first comprehensive compilation of these sugars in this series. About 200 are listed, and a measure of the rapidity of development in this field is that an unpublished list prepared by one of the authors now totals about 350. The volume also contains a review of the late H. O. L. Fischer's life and work, by J. C. Sowden.

Publications of this type do not warrant the usual type of review. Each article is a survey by an expert in the particular field, and as such is warmly welcomed by carbohydrate chemists in general. The articles are of a style that dates very little and because, when it is possible, they contain compilations of compounds with their properties, they have come to be the major source of reference in the field. Anyone with serious pretensions to be a carbohydrate chemist would do well sooner or later to spend the £70 required to purchase the complete series. The editors, M. L. Wolfrom, now editing his fifteenth volume, and R. S. Tipson, his ninth, deserve the largest share of the credit, for their zeal in enlisting contributors, in ensuring that all aspects of the subject are eventually covered, and in imposing their own high standards to ensure clarity and attractiveness of presentation. This laudable drive for high standards of presentation has, however, led them in the preface to describe as "deplorable" the "babel of initials employed for the designation of many of the starch hydrolases, in contrast to the more-meaningful names utilized for the glycogen hydrolases". In truth only two starch hydrolases, *R*-enzyme and *Z*-enzyme have been so designated. Others, which are not hydrases, also carry this type of name, namely, *D*-, *P*

Q-and *T*-enzymes. These names were deliberately initiated by Prof. Stanley Peat and the late Sir Norman Haworth to apply to enzyme preparations the precise function and purity of which it was thought unwise to speculate on by coining a specific name. The names were always intended to be replaced by explicit nomenclature when the purity and, particularly, the function of the enzyme preparations had been clearly characterized. The course of events has shown the wisdom of the use of 'initial' names. Thus *R*-enzyme has proved to be a mixture of two enzymes performing chemically identical functions, but on different substrates[1]; *Z*-enzyme proved ultimately to be identical with a well-known enzyme, α-amylase[2]. In the glycogen field, by contrast, one name for an enzyme has survived only because it became abbreviated to an 'initial' name, that is, *PR* enzyme. Speculation on the nature of its action has led it variously to be called *p*rosthetic-group *r*emoving enzyme, *p*rotein-*r*upturing enzyme and *p*hosphate-*r*emoving enzyme[1]. Similarly a glycogen hydrolase preparation, amylo-1, 6-glucosidase, was recently reported in *Nature* to depend for its action on two enzymes, a hydrolase and a transferase[3]. The best-intentioned of names "gang aft a-gley", and a policy of caution will impose less of a burden on the literature than one which provides names that later prove not to mean what they say. To me this policy of caution provides the most prudent way of tempering the advice attributed to one of the first editors of this *Advances* series, the late C. S. Hudson: "If you can't name it, don't make it!"

SPACE DYNAMICS

Space Flight

Vol. 2: Dynamics. By Krafft A. Ehricke. (Principles of Guided Missile Design.) Pp. xxi+1,210. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London: D. Van Nostrand Company, Ltd., 1962.) 230*s*.

THIS massive text-book could have been published as six 200-page monographs, each an important and pioneering contribution to the dynamics of space flight. Most authors would be well content to have written one of these six contributions. But Mr. Ehricke is cast in the heroic mould, and has accomplished single-handed what would normally occupy a large team of writers, each with a different point of view and style.

The first section of the book (Chapters 1–2) covers the dynamics of sub-orbital ballistic flight (including orbit-to-ground trajectories) and satellite orbits, including ascent paths and perturbations. It is a valuable feature of this and other sections of the book that Mr. Ehricke keeps the mathematics as elementary as possible, is clear in his exposition and gives a wealth of illustrations (more than 300 in all) in the form of diagrams and graphs of close grid: consequently, his book should be readily intelligible not only to mathematicians but also to physicists and engineers. Chapter 2 is, however, the least satisfactory part of the book because it is rather outdated: the discussions of the effects of the Earth's gravitational field and atmosphere seem to have been written about 1958 and, despite the addition of more recent titbits, are defective.

Chapter 3 deals with transfer between orbits about the same centre of attraction, from the solved problem of transfer between circular coplanar orbits to the recalcitrant one of transfer between non-coplanar ellipses. Mr. Ehricke's bold and pragmatic attack on the problem, using elementary concepts, is in refreshing contrast to the usual calculus-of-variations approach, which consists in writing down innumerable insoluble equations. Mr. Ehricke can perhaps be criticized for not making it clear that the rules-of-thumb he propounds do not always provide the answers; but it is far better to have some rules than none. He completes the subject in Chapter 4, which covers transfers between one central force field and another, and is largely concerned with hyperbolic orbits.

The next section (Chapters 5 and 6) discusses powered ascent paths and their optimization, taking into account thrust, lift, drag and the influence of gravity.

Chapter 7 is on low-thrust flight, which is important because in future interplanetary journeys the power unit is likely to be an ion or plasma rocket, with a much higher efficiency than a chemical rocket but a much lower thrust. This chapter runs to 233 pages and could stand as a book on its own, for it treats the subject more thoroughly than existing texts. Chapter 8 discusses lunar flights, including Earth–Moon flight paths, lunar circumnavigation, impact and landing, and lunar satellites. Again it is an impressively thorough survey, illuminated by much original work. The book ends with a long and systematic treatment of the dynamics of interplanetary flight, covering practical aspects of flights to the various planets—the best departure times for flights, the most convenient orbits, etc.

The book is excellently printed on good-quality paper, includes examples at the ends of chapters and lists of references (which are, however, almost all pre-1960). There is some vacillation about units of length, with nautical miles, feet and kilometres all making an appearance, but this is a minor defect. Misprints are very rare, and it is unfortunate that one of them affects the date given for the launching of *Sputnik* 1, which is in error by a year.

This book will remain as one of the enduring monuments of astronautics when most of the multi-million-dollar satellite launchings have been forgotten, and any organization which spends large sums on space activities will find it difficult to refute the conclusion that a copy should be bought for every appropriate member of its staff.

D. G. KING-HELE

THE EARTH SCIENCES

Mining for Metals in Wales

By F. J. North. Pp. viii+112+8 plates. (Cardiff: National Museum of Wales, 1962.) 12*s*. 6*d*.

The System of Mineralogy

By James Dwight Dana and Edward Salisbury Dana. Vol. 3: Silica Minerals. Seventh edition entirely rewritten and greatly enlarged by Prof. Clifford Frondel. Pp. xii+334. (New York and London: John Wiley and Sons, Inc., 1962.) 60*s*.

Volcanoes and their Activity

By A. Rittmann. Translated from the Second German Edition by E. A. Vincent. Pp. xiv+305. (New York and London: Interscience Publishers, a division of John Wiley and Sons, Inc., 1962.) 90*s*.

Introduction to Physical Geology

By Prof. Chester R. Longwell and Prof. Richard F. Flint. Second edition. Pp. 504. (New York and London: John Wiley and Sons, Inc., 1962.) 60*s*.

DR. NORTH'S *Mining for Metals in Wales* contains an account of the history of metalliferous mining in the Principality; together with a description of the geological mode of occurrence of the many varieties of ore that have been worked there. Metalliferous mining has now almost ceased in Wales, either for economic reasons, or through exhaustion of the sources. Attempts to revive the mining of lead and zinc were made a few years ago,

but none is now produced. The only mine still working is one in Glamorganshire, which produces iron ore (hæmatite). Yet, at one time or another in the past, gold, silver, copper, lead, zinc, iron and manganese ores were extracted in considerable quantities; and for a year or two there was even a small output of cobalt oxide. Indeed, the famous Parys Mountain mine in Anglesey is said to have been the largest producer of copper in Europe in the mid-eighteenth century; and the history of the mining of argentiferous lead ore goes back to Roman times. With the passage of time, mining techniques, too, have changed considerably, and Dr. North has something to say on this aspect of his subject. He has, in fact, condensed a very great deal of information drawn from many sources, often not easily accessible, into a short but very readable book with a number of attractive illustrations. The bibliography, which lists 164 references, is particularly valuable. Although the book has been produced by the National Museum of Wales primarily as a museum guide, for its newly established Department of Industries, it is, nevertheless, an important, authoritative, and much-needed contribution to the history of mining in Great Britain.

In 1915 a decision was made in the United States to prepare a completely new, enlarged and thoroughly revised (seventh) edition of Dana's classic *System of Mineralogy*. This was a major undertaking on which work has been proceeding ever since. Volume 1 of this edition, covering the elements, sulphides, sulpho-salts and oxides, was published in 1944; and Volume 2, which included the halides, carbonates, phosphates and other salts, in 1951. Volume 3, on the silica minerals, is the latest to appear. It has been written by Prof. C. Frondel of Harvard, who was a co-editor of the earlier volumes. It describes the properties and modes of occurrence of all the known polymorphs of silica, not only specific forms such as quartz, tridymite, cristobalite and more recently discovered species such as coesite and stishovite, but also the less well-defined varieties such as chalcedony, agate, opal, jasper, flint and so on. The text is well illustrated by line and half-tone illustrations and, as in earlier editions, much interesting historical matter has been included. This latest addition to the new 'Dana' will doubtless be welcomed by students and research workers in mineralogy and geology and by crystallographers and mineral technologists. Two further volumes are stated to be in the course of preparation, to complete the work. These will deal exclusively with the silicate minerals.

Volcanoes and their Activity is a translation of the second, revised and enlarged edition of Prof. A. Rittmann's *Vulkane und ihre Tätigkeit* (1960), which has been made by Prof. E. A. Vincent, now professor of geology at the University of Manchester. The book covers a wide field. The earlier chapters discuss volcanic activity in general, the products of volcanoes, and their structure and geographical distribution. In succeeding chapters the author discusses the physicochemical properties of magmas, the nature of magma chambers, and the mechanism of volcanic eruptions. In the last two chapters he elaborates a geological theory embracing vulcanicity, mountain building, magmatism, the Earth's interior, and the origin and development of the Earth. The theoretical views put forward in the latter part of the book are personal to the author and, admittedly, controversial. For this reason he states that his book should not be regarded as a text-book. Prof. Rittmann is, however, generally acknowledged as an authority on his subject. His book summarizes the results of many years of observation in the field; and it is on this work that his theoretical conclusions are based. His book, therefore, should be welcomed by all students of igneous geology, and volcanology in particular, especially because there is no equivalent book in the English language. The numerous figures illustrating the text add to its interest, many being reproductions from actual photographs of volcanoes and their products.

The second edition of Longwell and Flint's *Introduction to Physical Geology* is a thoroughly revised, enlarged, and largely re-written version of the original edition of 1955. A feature of this elementary text-book is its richness in line and half-tone illustrations drawn from many sources, including air photographs. Their number has been substantially increased, thereby adding to the value of the book for teaching purposes. Other changes include the introduction into the text of definitions of geological terms whenever they are first used, rather than in a separate glossary; and the addition of a brief summary of contents at the end of each chapter. The book should succeed very well in its main object; but the series of appendixes on the identification of common rocks and minerals, and on the properties of the latter, and on the use of maps and map symbols, are so short that their value is questionable.

ULTRA-PURIFICATION OF SEMICONDUCTOR MATERIALS

Ultrapurification of Semiconductor Materials: Proceedings of the Conference, Boston, Massachusetts, April 11–13, 1961. Edited by M. S. Brooks and J. K. Kennedy. Pp. 655. (New York and London: The Macmillan Company New York, a Division of The Crowell-Collier Publishing Company, 1962.) 12.50 dollars; 94*s*.

THIS volume is a report of the Boston conference held in April 1961 and contains forty-nine papers. The title is perhaps a little misleading, in that many of the materials considered are not themselves semiconductors, but are used in the preparation of semiconductors or semiconductor devices. The papers are divided into three groups dealing with chemical preparation and purification analysis, and the physical methods of preparation. The first group of papers contains information on the purification of silicon, boron, bismuth, tellurium, gallium, rare earths, indium, antimony, and arsenic. It begins with an excellent review paper by Fuller of Bell Telephone Laboratories detailing progress so far on the purification of elements and compounds. The paper also discusses analytical methods for trace impurities and contains a most useful bibliography of fifty-one papers. The first three papers of the group deal with the purification of silicon from silicon tetraiodide and silicon hydride. The fourth paper deals with the preparation of boron from boron trichloride. A paper on organometallic compounds in the preparation of high purity metals is very complete and has 151 references. The last two papers in the section deal with chromatographic methods for purification, the starting point being organometallic compounds.

The second group of papers starts with a review by G. H. Morrison dealing with activation analysis, emission spectroscopy, and mass spectra. In this section there are eight papers dealing with emission and mass spectroscopy to detect impurities in elements and compounds, mainly of the III/V class. One is left with the impression that when materials are pure enough to be interesting as semiconductors these analytical techniques are already stretched to limit of sensitivity.

The third group of papers, which deals with physical methods of preparation, starts with a section on zone-purification processes, mainly from the point of view of the physics of the zone-refining process. The second section on crystal growing, deals mainly with silicon and III/V compounds, while the final part contains miscellaneous papers mostly concerned with semiconductor materials.

This book will be most useful to the physicist or chemist working in the field of material preparation, both semiconductor and other related materials. The bibliographies attached to many papers are in themselves most valuable.

A. A. Shepherd

COMMONWEALTH UNIVERSITIES CONGRESS, 1963

By Sir JAMES COOK, F.R.S.
Vice-Chancellor of the University of Exeter
J. S. FULTON
Vice-Chancellor of the University of Sussex
AND
Dr. D. G. JAMES
Vice-Chancellor of the University of Southampton

THE Ninth Quinquennial Congress of the Universities of the Commonwealth was held in London during July 15–19. The first Congress of the Universities of the Empire had been convened in 1912 by the University of London, and at that Congress a decision was taken to establish a bureau of information for the Universities of the Empire. The office of the Universities Bureau of the British Empire was opened in London the following year. In 1948 the name was changed to the Association of Universities of the British Commonwealth, which was incorporated under the Companies Act. A major function of the Association has been the organization of further congresses which the Congress of 1912 recommended should be held at five-yearly intervals. Congresses were, in fact, held in 1921, 1926, 1931, 1936, 1948, 1953 and 1958.

It was with such circumstances in mind that London was chosen as the venue of the recent Congress, a gala occasion which marked the jubilee of the Association. It was more than fitting that the University of London played the part of host and did so very worthily. The president of the Congress was the chancellor of the University, H.M. Queen Elizabeth the Queen Mother, and the deputy president was the vice-chancellor, Dr. P. S. Noble. The chairman of the Association in its jubilee year was the indefatigable principal of the University of London, Sir Douglas Logan. To him is due in no small measure credit for the outstanding success which marked every phase of the Congress.

Shortly before the Congress, H.M. The Queen had approved the grant of a Royal Charter to the Association, to be known henceforth as the Association of Commonwealth Universities. The charter was formally handed over to the chairman by the Queen Mother at the Congress dinner on July 17. During the period of the Congress the necessary steps were taken to wind up the Association of Universities of the British Commonwealth.

Among the numerous illustrious vice-presidents of the Congress were four royal chancellors of universities, three of whom (H.R.H. The Duke of Edinburgh, H.R.H. Princess Margaret and H.R.H. the Princess Royal) honoured working sessions of the Congress with their presence. The Queen gave a garden party for members of the Congress and their ladies. Other social highlights included receptions by the Government, by the Corporation of London in Guildhall, and by the Twelve Great City Companies of London, as well as a reception by the University of London. So there were many indications of the unique character of this gathering of about 1,000 people. They included 380 delegates from 110 member university institutions of the Association supported by numerous observers and guests, among them representatives of kindred organizations such as the Association of American Universities, the International Association of Universities and the National Committees of University Rectors in Western Europe.

At the general meeting of the Association held on the last day of the Congress an invitation to hold the next Congress in Australia in 1968 was accepted with gratitude. This conforms with the principle agreed at the Eighth Congress in Montreal in 1958 (*Nature*, 182, 1283; 1958) that alternate congresses should be held in Commonwealth countries other than the United Kingdom.

An innovation at the recent congress was the splitting-up of its members into three discussion groups (designated *A*, *B* and *C*) which met simultaneously during three sessions. These three group discussion sessions supplemented the three plenary sessions. In this way it was possible to cover a larger range of topics than in previous congresses. It was found, as was expected, that the more intimate conditions of the group discussions facilitated free exchange of views.

Diversity of Universities

At the first plenary session on July 15, Sir Eric Ashby gave the inaugural address on "The Diversity of Universities in the Commonwealth". In his characteristic and inimitable way he painted a vivid and graphic picture, from an ecological point of view, of the evolutionary pattern of Commonwealth university development which had led from a very few prototypes to a wide variety of forms of institution—universities which had adapted themselves to their several environments. The process of change is far from complete, he thought, and in the new African universities is likely to be far-reaching. Universities do change and become adapted to the communities they serve, in spite of their common origin and their desire to remain on an international 'gold standard' of learning. London and Manchester, Michigan and Cornell, all in their origin based to some extent on German universities, are now very different from German universities as they are from each other. So, too, the universities of India and Australia have diverged from one another as they have from their common English ancestors. Moreover, the universities of Canada, diverse among themselves, have moved away from the French and American systems on which they were based. "The constitutions exported to Ibadan, Makerere and Salisbury were designed for nineteenth-century Manchester . . . nothing is more certain than that they will change."

Leaving diversity in the structure of universities, Sir Eric turned his attention to diversity in the student body. He suggested that of three children born in 1945, in Toronto, in Sydney and in London, the chance that the Canadian is now a full-time student is about 1 in 6, for the Australian it is 1 in 9, and for the Londoner 1 in 20. These differences represent, he claimed, differences in the social philosophy of education between the three countries. Higher education can be regarded as a national investment, as a kind of 'consumer-goods' conferring status, like television sets and cars, or as a civic right. There is a mixture of all three points of view in any one country, but with varying proportions of the ingredients. In Britain higher education is not yet conceded as a right, but is sought as a 'consumer good'. This, or the notion of a civic right, would be dangerous in the new States where, Sir Eric inferred, investment in high-level manpower is the most important present requirement. "However

diverse our universities are it is our common task to create in them an environment for higher education which promotes continuous innovation and renewal. If universities fail to do this, Western civilization will decay."

United Kingdom University Developments

In the other two plenary sessions members of the Congress discussed "Significant University Developments in the Commonwealth, 1958–63". One session was devoted to the United Kingdom and the other to Nigeria. The first speaker on the United Kingdom universities, Sir William Mansfield Cooper, reviewed the changing scene at home since the Eighth Congress, from the point of view of a vice-chancellor who had become chairman of the Vice-Chancellors' Committee within the review period. Sir William's address was read for him by Mr. V. Knowles, registrar of the University of Manchester, Sir William having been summoned to Buckingham Palace to receive the accolade. In his rather gloomy and somewhat cynical survey of the quinquennium with its frustrations, he referred to the mounting pressure for university places which had stimulated the establishment of the Universities Central Council on Admissions. On student quality during a period of rapid growth, Sir William thought that the pure scientist has few complaints, the technologist has more, while the arts man is most likely to be depressed. He suggested reasons for these faculty variations and then recounted the familiar story of inadequate financial provision to meet the needs of an expanding university programme. In spite of the anxious period through which the universities had passed during the past two years, Sir William felt that the University Grants Committee and the system which it represents are now more strongly established than at the beginning of the quinquennial review period.

Sir Nevill Mott spoke about research in the universities and repudiated the view that university research is just an expensive luxury to stimulate the dons and keep them up to date. He thought that both pure and applied research should be put in universities whenever possible and commended developments such as the links between Oxford and Harwell and the recent appointment of five members of the staff of the National Engineering Laboratory to be visiting professors at the Royal College of Science and Technology in Glasgow (see *Nature*, **198**, 940; **199**, 843 (1963)). See also p. 1137 of this issue. While welcoming the central service for universities provided by the National Institute for Research in Nuclear Science, Sir Nevill questioned the assumption that in some fields of research the necessary facilities are too big for a university. The implication that concentration of major facilities in selected universities necessitates more direction from the top did not greatly alarm him. Academic freedom means the right to argue, and, provided universities retain this right, it is perfectly consistent with their character that they should welcome suggestions from Government about lines of research which the national interest requires.

The third opening speaker on the United Kingdom universities, Dr. C. H. Wilson, principal of the University of Glasgow, gave an interesting survey of the establishment of seven new universities and outlined the many respects in which they contrast with the earlier model of British university. From the Government's point of view, they represent a national investment, designed to produce an additional 21,000 university places in the mid-1970's. Dr. Wilson suggested that they represent just as much a demand in the older universities for innovation in the university scene. The Academic Planning Boards which have fashioned their character have sought to diversify their degree systems and to diversify their government. However, it is in middle-age rather than in youth that the most inventive ideas are available and Dr. Wilson thought that it is from those already established in universities that new ideas have to come. He had been impressed by the vastly greater conservatism on the part of the scientists than was the case with non-scientists. The first-degree systems in science are more intractable to change than in arts and social sciences. Dr. Wilson ended by reference to the proposed largely residential character of the new universities. "I ask myself, when I look at the cost of this and begin to quantify it for a large number of foundations, how long can it go on in quite this way? I ask myself, too, whether the demand by undergraduates for residence will be for the kind of residences we have built."

It is not possible here to do more than touch on a few of the many interesting points brought out in the ensuing lively discussion. Mr. J. S. Fulton (Sussex) referred to the plans of his University and the stimulating effect on brilliant young staff of participating in such an experiment. Sir Malcolm Knox (St. Andrews) deplored the increasing threat to the distinctive character of universities which he thought must end in impoverishment of our academic life. He suggested that many young people needed training of a kind given admirably at technical institutions of various kinds. They were not academically minded, and should not be brought into the universities. Sir Malcolm was also disturbed about the way in which the distinction between a university and other forms of education is being blurred and by the way in which universities are being thrown into the political arena. This view of the "voice from the past" was contested with varying degrees of heat by several subsequent speakers who acknowledged the designation of expansionists. Dr. J. P. Baxter (New South Wales) wondered why we had established a large number of small new institutions instead of increasing the size of existing universities to a more economic level and also why we placed these new institutions in cathedral cities "away from the throbbing heart of industry". Dr. Brynmor Jones (Hull) directed attention to the administrative demands which rapid expansion makes on academic staff to the detriment of their opportunities for research. Prof. R. F. Treharne (Aberystwyth) would like the universities to set up their own machinery for deciding how schemes of teaching and research should be distributed among them—perhaps an inter-university committee to advise the Government. Present arrangements tend to concentrate resources in a few places and the smaller institutions are overlooked. Dr. M. R. Siddiqi (Sind, Pakistan) directed attention to some disadvantages of the system of affiliated colleges in India and Pakistan and thought that ultimately these colleges should be given university status. The Ven. H. Ratanasara (Vidalankara, Ceylon) was anxious that the new universities should be protected against external pressures.

Nigerian University Developments

The fascinating story of university development in Nigeria during the past five years was unfolded at the third plenary session on July 19 by three opening speakers —Sir John Lockwood (London), Dr. Davidson Nicol (Sierra Leone) and Dr. E. Njoku (Lagos). As a member of the Ashby Commission, Sir John had had some share in promoting this development. In 1958, he reminded us, there was a single university institution—University College, Ibadan. Now there are five independent universities. The student population has increased two and a half times, and the rate of growth promises to accelerate. Sir John described in outline the character of these new universities and referred to the decisive part played by the University of Nigeria at Nsukka in fostering re-thinking about the nature and functions of African universities. He mentioned the striking fact that, in two regions at least, 40 per cent of the national budget is spent on education. This illustrates Nigerian determination not to neglect or waste the talent of its people. Training of teachers is in the forefront of the university programmes and all the universities are showing determination to

become genuinely Nigerian institutions. This is exemplified by proposals for the establishment of Institutes of African Studies.

Dr. Nicol reminded the Congress of the part played by the Inter-University Council for Higher Education Overseas and by the Universities of Durham and London in promoting university development in Africa. He discussed the need for a new philosophy of higher education in Africa and the ways in which fruitful co-operation between African and other Commonwealth universities might develop. Staff secondment will be needed, and facilities should be provided for African staff to participate fully in the work of the departments of universities in other countries as part of their training as university teachers. The African universities must develop their graduate schools, and here, too, co-operation with Commonwealth universities will assist. They must adapt and extend their curricula to suit their environments. Dr. Nicol reiterated the need to develop African studies, in which a promising start has already been made.

After commenting with approval on the fact that he had been preceded by two non-Nigerians, Dr. Njoku directed attention to the very rapid rate of change in the Nigerian university scene. The time-scale seemed different from that of the rest of the world. Although Ibadan's rate of growth had been the fastest of the institutions in the British post-War overseas territories, in Nigeria itself the rate was considered far too slow. Last session's enrolment of nearly 1,800 will increase rapidly. A measure of the new time-scale is given by the University of Lagos. Its Act of Incorporation was passed in April 1962. The inaugural meeting of the Provisional Council, at which Dr. Njoku was appointed vice-chancellor, was held in June, and the first students were admitted four months later. The Nigerian target is 10,000 students by 1970. The establishment of a Manpower Board and a National Universities Commission have been important developments and a very significant one has been the great interest aroused outside Nigeria in its problems of higher education.

Prof. C. T. Ingold (London) referred to the part played by the London University Senate Committee on Colleges Overseas in Special Relation, and directed attention to the continuing great need for the Commonwealth universities to second and lend teachers to Nigeria. Dr. N. S. Alexander (Ahmadu Bello University) stressed how much Nigeria has to offer the expatriate—immediate results to be seen; surplus of research problems. In reply to Dr. R. Craig (Rhodesia and Nyasaland), Dr. Alexander suggested that both research workers and teachers are required; there is a place for the young man, recently graduated, and also for older people approaching retirement. Dr. H. M. Taylor mentioned an informal agreement recently made for interchange of staff between Keele and the University of Nigeria.

Group Discussions

Three general themes were chosen for the three group discussions. In Group *A*, the role of the layman in university government was discussed in three aspects: in educational policy, in finance and in public relations. The background to all these discussions was described by Dr. H. C. Coombs, governor of the Reserve Bank of Australia, and pro-chancellor of the Australian National University, when he said at the outset that universities must ultimately be accountable to the society of which they form part: the social isolation of universities is undesirable, and because of their dependence on public funds impossible. He went on to say that the layman's role had two sides to it. "Laymen", he said, "should see themselves within the University as representatives of the community, observing the University in action and seeking, within limits, to ensure that, allowing for the special character of the University as an institution, its social purposes are performed adequately and at reasonable cost. Outside the University, their role, as I see it, is to stand as an interpreter of the University to the community and to its government, which cannot adequately hope to know its work or grasp its problems, and as a guarantor that, consistent with its special role and ways of work, the University recognizes and accepts its role in society and its ultimate accountability for it." It would scarcely be possible to find a better short statement of the value of the layman to universities.

Dr. Coombs spoke with particular reference to the role of the layman in the fashioning of the university's educational policy. He was very conscious that in this field the role of the layman must be limited; but even here, he said that the layman may well contribute by "asking questions and inviting more detailed examination" of educational policy; and the President of Toronto spoke of the need of maintaining "a dialogue" between layman and academic, if the universities were to have their proper place in society.

Dr. John Deutsch, formerly secretary of the Treasury Board of the Government of Canada, and now vice-principal of Queen's University, Kingston, introduced a discussion on the importance of the layman for the fashioning of universities' financial policies. If the role of the layman in educational policy is to ask questions and compel discussion, his role in financial policy is more positive: he has a range of experience of the utmost value to university administrators; and Dr. Deutsch had no difficulty in illustrating this. But he went on to speak of "partnership" between "professional and layman": "the role of the layman", he said, "is not to govern or impose his will . . . but to help to create conditions in which academic purposes of the institution can be achieved more fully and its integrity can be defended more surely". The discussion on the layman in public relations was introduced by Sir Douglas Robb, chancellor of the University of Auckland, who brought out, in greater detail, the importance of the layman in interpreting, as Dr. Coombs had said, the university to the layman.

It may be said that, in general, the role of the layman in university affairs was so wisely expounded by Dr. Coombs, Dr. Deutsch and Sir Douglas Robb that in the long and full discussions which followed their talks, no difference of view between layman and academic was expressed. It became more clear than ever that throughout the Commonwealth the services rendered to universities by laymen is incalculably great.

The general subject of discussion in Group *B* was the university student. In the three sessions the topics covered were: (*a*) selection and admission; (*b*) postgraduate training; (*c*) amenities, housing and community life. The second of these—given a comprehensive and challenging send-off by Mr. Nöel Annan (Cambridge) and Sir Patrick Linstead (London)—was perhaps not surprisingly the most cohesive. Whatever their differences in other respects, universities everywhere share together a concern for the pursuit of truth. Thus the successful training of the postgraduate in the spirit and the methods of research, his apprenticeship to the higher scholarship, is a vital interest to them all. The outside world needs, no doubt, men and women trained in schools of research at universities; but the universities most of all need them for their own survival and fertility in the future. Inevitably there arose in discussion the sharply divisive and perennial issue, whether the Ph.D. can be fully effective as a means of training if its subject is, apparently, "trivial" or of "no importance". Otherwise, the discussion revealed the similarity of the problems raised by the rapid growth in the number of postgraduate students in the universities of the Commonwealth and the United States; the part that should be played by the postgraduate in teaching; the need for adding to the traditional thesis other forms of training in research methods; the effect of the increase in the number of postgraduates on the

development of university research, particularly if they attract growing support from foundations and Government research agencies; the language barrier to the free movement of postgraduate students. A number of practical suggestions—chiefly for the improvement of information about the facilities available for research—promised greater co-operation between different parts of the Commonwealth in the future.

The first and third discussions revealed greater divergencies. Again, this was perhaps to be expected since neither selection and admission nor what comes under the heading of community life can avoid raising explicitly or by implication the fundamental issues about the function and purpose of a university. Should qualifications for admission and methods of selection be directed solely to the choice of those whose interests are 'academic', an intellectual *élite*; or designed to include within a university's membership a much wider range of gifts and qualities. The answer to these questions rests on the view taken about the nature of the university itself and of its place in modern society. Is its primary aim the production of the scholar, the Fellow of the Royal Society ? Is it to build up a bank of professionally qualified persons needed by an underdeveloped country if it is to reach the point of economic 'take-off' ? No such stark opposition of view was made explicit in the discussion, but implicit assumptions, such as these, coloured much of the discussion about the examination as a test for entry; its value in predicting success at the university; the merits and demerits of the open-entry system of the United States; and the social consequence of failure under the rigorously selective system as practised, for example, at 'Oxbridge'.

The third and last discussion ranged widest of all. There were those who took for granted, so it seemed, that the modern undergraduate at entry was fundamentally perverse and irresponsible, overdeveloped intellectually and socially as well as emotionally immature; those who defended him warmly against the criticisms of his elders; those who felt that he (especially the 'new student') was too much 'of the world' already and needed to be withdrawn during his university years from the pressure and hurly-burly of ordinary existence; for them the hall of residence on the university campus was the right answer; those, on the contrary, who felt that segregation —whether from family or other social ties—and an artificially high standard of living were wholly bad; these approved of the civic university whose students live with their own families. These differing views reflected in some degree the difference between old and developing countries; but they divided also even those from the same countries and environments.

But all—segregationists and integrationists alike—united in one aim—to prevent, if possible, the university from turning out a lop-sided individual, intellectually precocious but humanly underdeveloped. There was a general welcome for the plea—put forward at more than one session by Dr. Furneaux of the University of London —for the universities to take seriously the task of 'knowing themselves', in particular for research and still more research into the psychological forces that mould, and the stresses that beset, the contemporary student, and into his special needs if he is to make the best possible use of his opportunities and of society's investment in him.

Group *C* discussed co-operation among universities of the Commonwealth and consideration was given to: (*a*) regional studies as an academic discipline; (*b*) intercommunication between Commonwealth universities; (*c*) the Commonwealth Scholarship and Fellowship Plan. Regional study, according to Dr. J. H. Parry (Swansea), who introduced the discussion, does not define a subject-matter very precisely. The Commonwealth is a region, from the point of view of a historian, a political scientist or a constitutional lawyer, but not from the point of view of a geographer or an anthropologist. The U.S.S.R. looks a much tidier subject from a geographer's point of view, but not from that of a historian. Considerable controversy was aroused by Dr. Parry's claim that regional studies are not for undergraduates because of their superficiality and lack of precision, with the concomitant danger of turning the ill-informed into the misinformed. Prof. R. J. M. Wight (Sussex), the second opening speaker, challenged this view and described the development of European studies at Sussex. In the subsequent discussion illustrations were drawn from Islamic studies, Far Eastern studies, and African studies, and while there was general agreement about the value of regional studies there was a sharp cleavage of opinion about the level at which they should be undertaken. Dr. Siddiqi (Sind, Pakistan) made the interesting, if obvious, point that regional studies are applicable only to such a range of subjects as languages and the social sciences, and not to such university disciplines as mathematics and the sciences. The main value of regional studies was held to reside in their ability to co-ordinate a range of different disciplines and to break down subject barriers.

In the second session, Prof. P. M. S. Blackett (London) opened the discussion by stressing the need for the supply of expatriate staff for overseas universities, which now have some 700 British-born teachers, representing about 6 per cent of our total complement of university teachers. He referred to the Committee on University Secondment, to the problems to which reference was afterwards made by its chairman, Sir Charles Morris, and one of its secretaries, Mr. F. P. Dunnill, of the Department of Technical Co-operation. Reference was made to the 15 prestige awards announced in the House of Commons on the previous day, to the need to inculcate the idea that a period of overseas service will count as a virtue and to the need to deal with such problems as the education of children of seconded staff. In referring to the need for research funds for staff on secondment, Prof. Blackett asserted that the Department of Scientific and Industrial Research has the right, which has not been exercised, to provide grants for this purpose. He also suggested that greater initiative should have been taken by the Government in promoting staffing of overseas universities. Inter-communication by means of persons was also the theme of the second opener, Sir Robert Aitken (Birmingham), who gave as a prescription for a university staff: (*a*) a majority from the home country; (*b*) some from other Commonwealth countries; (*c*) a few from other countries. Complete nationalization of a university staff is undesirable, especially in a developing country.

An authoritative account of the working of the Commonwealth Scholarship and Fellowship Plan in the United Kingdom was given by the Earl of Scarbrough (chancellor of the University of Durham), the first chairman of the Commonwealth Scholarship Commission. The awards so far made totalled 1,102, of which 584 (from 43 countries) have been taken up in Britain and 295 in Canada. The number of current awards in the past academic session was 820 of which 467 were held in Britain. So the plan is in sight of reaching its objective in numbers, 1,000 scholarships at any one time—500 in Britain and 250 in Canada. Of the 142 scholars whose awards in the U.K. ended last session, 43 have taken up academic posts. Lord Scarbrough thought it important to maintain the essential character of the Plan—educational opportunity at the highest level. He also stressed the importance of flexibility, to meet the varying needs of the Commonwealth countries. The Oxford Conference in 1959, at which the Plan was formulated, envisaged some awards to junior members of teaching staffs who would undertake teaching as well as research. This part of the scheme has not been implemented. Is it attractive to universities ? Some speakers urged that funds should be made available for such awards and also for awards to assist the building up of research schools. It was pointed out, however that the object of the scheme is to benefit individual

rather than universities and that there are other schemes to provide teachers. The view was expressed by critics that the Plan has tended to impoverish research schools in less advanced countries and to enrich research schools already well provided with postgraduate students of high quality. Although extraneous needs should not be allowed to dilute the Plan, which has been widely welcomed in Commonwealth countries, it was recognized that funds are needed to supply other needs, including the support of research schools in new universities overseas.

In the four days following the London Congress the executive heads of the Commonwealth universities, accompanied by the American university presidents, held further meetings in the University of St. Andrews, where the topics for discussion were "Secondment of Staff", "Governing Bodies of Universities", "Development of University Staff Associations" and "Aspects of University Expansion". It was not the purpose of either this meeting or the larger Congress to pass resolutions or to make recommendations. There was general agreement, nevertheless, that the exchanges of views and experiences had been of great value. A full report of the proceedings of the London Congress will be published by the Association of Commonwealth Universities.

COLLEGES OF ADVANCED TECHNOLOGY IN BRITAIN

By Dr. E. G. EDWARDS
Principal, Bradford Institute of Technology

THIS article is being written a few weeks before the appearance of the report of the Robbins Committee. The new master plan for higher education which we expect to emerge will, *inter alia*, re-define the role of the Colleges of Advanced Technology and bring their future into sharper focus. This is, perhaps, the last occasion when it is possible to survey the progress and perspectives of these Colleges in the relative calm which follows the initial phase of emergence and rapid growth and precedes a new period of intense activity and development.

It is still difficult to understand the long induction period between the Percy Report of 1945, which made the basic recommendations for the new strata of colleges and their designation as Colleges of Advanced Technology in 1956. The need was obvious and universally acknowledged, and was not being filled. Britain emerged from the Second World War into a world where its survival depended on creating a technologically advanced industry. Successive surveys of scientific and technological manpower revealed not merely the acute shortages, but, more seriously, the continued underestimation of our future needs[1]. However, the problem was not only one of quantity, but even more of quality. The basic engineering industries of the country, on which the modernization of all our industries depends, were particularly slow in increasing their proportion of professional engineers and technologists[2]. Equally serious is the fact that, of all the industrial countries, we are the only one in which the majority of our professional engineers are still trained by part-time and evening study[3] with all its attendant scientific limitations and cultural narrowness.

Finally, our existing higher educational system and the structure of secondary education which serves it has remained seriously restrictive in two ways particularly significant to the present theme. First, it has failed to bring into higher education more than a minority of those with the latent ability, particularly from the families of manual workers[4], and, secondly, it has failed to break down the cultural and social barriers between talent and technology[5]. For the majority of people, education, including higher education, is a prelude to practical activity. They will spend the greater part of their working lives in industry in its widest sense, including commerce and social organization. Technological education is concerned with serving two related social purposes: first, to enable its students to make the most fruitful and creative contribution to the industry they serve and, secondly, to enable industry to make the fullest and most creative contribution to the life of society.

We are thus concerned with a dynamic concept of industry with the continuous evolution of new methods and social purposes. It is clear that technological education cannot be restricted to some narrowly vocational role of fitting a human cog into a pre-existing and unchanging machine. The men we train are going to change industry and interpret its function within society. It is by these standards that we need to assess the past and present shortcomings in our education of technologists and the present attempts and future perspectives in developing new methods.

The Colleges of Advanced Technology were originally a group of the larger technical colleges. Most of these were founded at the turn of the century, and for the first fifty years were largely concerned with training engineers and other technologists by the methods prevailing in Great Britain, those of evening and, latterly, part-time day courses for students apprenticed in industry. This had the advantage of bringing the Colleges into close contact with industry. Their staffs were largely recruited from industrial technologists. The dichotomy between science and its industrial application which has so seriously affected full-time education and research was largely absent. On the other hand, the narrowness of the part-time system, its scientific limitations and the high wastage imposed by the severely intense nature of the courses weakened and restricted not only the Colleges but also the whole of our technological development. At the beginning of the post-war period, the Colleges had developed a supplementary stream of full-time students, often studying for external degrees or professional qualifications. Research developed more slowly and unevenly, mainly concentrated in the science departments. Nevertheless, the public image of even the largest of the Colleges was that of a night school of higher education, devoted on one hand to the vocational training of engineers and, on the other, to reclaiming in all fields talent that failed to find its way into the universities.

This was the background which the Colleges had to re-assess after their designation as Colleges of Advanced Technology in 1956. The main immediate objectives were: to retain and extend their interaction with industry while removing the limitations of previous methods of education; to develop new forms of undergraduate education appropriate to the wider needs of industry; to expand their staff as rapidly as possible and to improve their quality while continuing to emphasize the value of responsible industrial experience; to expand their research activities to a comparable level, but with a different emphasis, to that of the larger faculties of science and technology within universities; to widen the range of their studies and researches to cover all those mainly concerned with their central objective of providing a future leadership for industry.

In the rest of this article an examination is made of the progress which has been made in the attainment of these objectives and the new problems and perspectives that are

emerging as a result. During the period since designation the eight original Colleges, later joined by two others, have multiplied their full-time undergraduate population from about 3,500 to more than 10,000; their full-time teaching staff has almost doubled to a total of about 1,800, and the majority of the new staff have had both industrial and significant research experience. Research which was originally concentrated in certain subjects has now spread to virtually all the departments in all the Colleges. A substantially new form of undergraduate education, the 'sandwich' course for the Diploma in Technology, involving a close interaction of industrial and academic experience, has been soundly established during the period, the numbers increasing from less than 200 to nearly 6,000.

It would now be useful to examine some of the features of this development in greater detail. Consider first the question of co-operation with industry. The new type of sandwich course has been fashioned largely in the Colleges of Advanced Technology, where 75 per cent of the students are enrolled, although the overall approval of the courses has been under the ægis of the National Council for Technological Awards (N.C.T.A.). While such courses have existed in some form or another for many years, the development of the Diploma in Technology in the past seven years has been new both in scope and in nature. It originated from a general attempt by individual colleges and industry to attract a better level of student into the professions concerned with industrial engineering. Indeed, during the initial period perhaps one of the most significant problems has been the methods of selection for such courses. The general requirement is equivalent to university entrance level; but over and beyond this the objective is to find some method of both attracting and selecting the kind of students who are going to benefit most from the blend of industrial and academic training involved. As the investigations in ref. 5 have shown, the grammar schools have tended to send only their second- or third-best students into engineering technology at the universities and, in some schools, the initial reaction to the new type of course was to place it even further down the list of priorities. Fortunately, increasing contact between the Colleges and the schools has helped to disperse this illusion, and the proportion of good students who put down the Diploma in Technology course as first choice is rising significantly. Nevertheless, the problem of selection has a number of special features to it. In the first place, frequently both industry and College have to be satisfied with regard to the likely suitability of the student. This is certainly the case of works-based students, but is advisable even in the case of college-based students. Otherwise, the College may accept students and find it not possible to get them past the personnel and training officers in industry for the purposes of industrial training. Fortunately, this does not necessarily involve an elaborate apparatus of dual interviewing; it does require an assessment by the College or industrial staff concerned of the qualities likely to be required by the other partner in the enterprise. The College tutor interviewing students has to assess the likelihood of the student being capable of making a success of industrial training and a subsequent industrial career, as well as having the qualities of intelligence, critical ability and imagination required by the disciplines of the academic course. Up to the present, these methods of selection have been evolved and could only be developed by empirical means. As might be expected, the first few years tend to show a correlation between performance and initial examination successes in those courses, such as mathematics, where one would expect a strong influence of innate ability. On the other hand, in the case of engineering and some branches of applied science, no such simple correlation obtains, for example, between marks in a General Certificate of Education (Advanced Level) examination and performance in the course. However, there is empirical evidence that success in the course, if not distinction, is frequently bound up with the early indications of the degree of committal to an industrial career.

A feature of the Diploma in Technology course is that it permits the entrance of Ordinary National Certificate students as well as grammar school students. A precaution here is that it is normally required that the Ordinary National Certificate students must have a certain minimum mark in their final examinations. It is significant that at the Birmingham College of Advanced Technology in the first seven years of some Diploma in Technology courses in engineering, the proportion of first-class honours was very markedly higher among Ordinary National Certificate students than those recruited from the grammar schools, in spite of the fact that the latter would have had a much stronger basis for the scientific and mathematical studies which are ultimately a very strong feature of the course.

These first experiences with different streams of entrants demonstrate the previously suspected existence of reserves of ability for higher education which could escape the normal processes of university selection. Nevertheless, the large majority of future students will inevitably be recruited from secondary schools at the age of eighteen or more. It is therefore desirable that some methods be devised of projecting into the schools themselves the capacity to cultivate and detect future ability in technology. Part of the answer may lie in the development of new methods of teaching mathematics and science in such a way as to avoid an excessive pre-occupation with them as things in themselves, in favour of the concept of them as tools for application to real situations. The research being initiated by such foundations as the Nuffield Trust is of considerable significance here and should be greatly extended. A longer term contribution may lie in the recruitment into the schools of science and mathematics teachers with industrial and technological experience and the potential role of the Colleges of Advanced Technology in this field will be mentioned later.

The sandwich course system of undergraduate training, though not the only method used by the Colleges of Advanced Technology, is a major feature of the work of most of them. It is therefore necessary to re-examine briefly the concepts on which this mode is based and the factors likely to affect its expansion. Most scientists and engineers are employed in industry (in its widest sense) and the large majority of these are concerned directly with the application of science and technology in practice. Hence a method of education deliberately conceived to serve these objectives could, if successful, eventually become dominant and the Colleges face the ultimate role of educating the majority of industrial engineers and applied scientists. This could mean the multiplication of their present output by a large factor, possibly as much as ten.

The viability of the sandwich method depends on a degree of co-operation and interaction with industry which is at present only in its initial stages. To survive in the long term, it must prove to be qualitatively sound and economically justifiable. The qualitative factors depend on the devising of an educational system which produces a man who is committed to (or involved with) the idea of serving the community through the application of science in industry. He must, nevertheless, have a sufficiently independent standpoint and critical and imaginative ability to be an initiator of change whenever it is desirable or necessary. No single system of interaction of industrial and college experience will serve all technologies. The main problem is to interact the two experiences in such a way that they reinforce each other to the maximum extent. Individual Colleges are accumulating experience on this through the continuous contact between their staffs and their industrial counterparts, particularly during the industrial training periods. It

begins to emerge that an exact correspondence of experiences is both impracticable and unnecessary. What is necessary is that each part should engage the initiative of the student and that the industrial experience in particular should involve him in making a real contribution to a team engaged on a significant project. The inculcation of techniques, though necessary in certain technologies, is secondary to the main purpose of the maturation of a concept of science in its application and a comprehension of the many-sided co-operative effort needed for its prosecution. The viability of the sandwich course depends on the assumption that this process can take place concurrently with scientific education rather than exclusively after it. An important feature is that, even though the industrial and academic periods form a single course of training, they are nevertheless separated into significantly long individual periods (six months or one year). Research is needed into the effect of this alternation of different though related experience. Preliminary investigation shows that in many cases it can lead to an enhancement of the critical outlook to both sets of experience. At the same time, it can provide an immunization against the kind of disillusion which afflicts so many graduates who enter industry for the first time at the end of their university study.

The question of the viability of the high-level sandwich course from an economic point of view is of the highest significance. During the past year, there have been distinct signs of a decrease in the expansion of industrial places for students, and the reason given in nearly every case is economic—the charge on industry for providing the maintenance expenses of the student. From the national point of view, there is no reason why the sandwich method of training should be more expensive than a full-time education followed by some kind of postgraduate apprenticeship or induction period. Indeed, in so far as there are some initial parts of industrial experience which are inevitably routine in character, it is clearly more economical to finance them at the level of a student maintenance grant than at the salary of a graduate technologist. However, the present method of finance of sandwich students, which throws the burden of maintenance of students on firms, who, in many cases, may never employ the students concerned, may now become a major obstacle to expansion. If university students are supported wholly by the State, it must be willing to give the same support to sandwich students and perhaps to participate in the cost of industrial training. The simple immediate measure would be to make annual maintenance grants for sandwich course students from public funds to cover the period of the full twelve months for which they are in training, instead of a maximum of six months as at present. The industrial contribution to the cost should either come from taxation or a levy covering the whole industry.

The sandwich course has been dealt with in some detail to show the extent to which co-operation with industry is an intrinsic part of the life of the Colleges. Nevertheless, whatever evolution the methods of education will undergo, the same need will be evident though it may be expressed in different forms. Mention has been made of the extent to which the Colleges draw their staff from industry. During this emergent period, they have been relatively successful in attracting young men of high quality, and this has partly arisen from the fact that the particular method used for establishing salary scales in technical colleges has led to very favourable conditions for young men of lecturer level in the age-range 26–32, as Prof. Irving has already pointed out[6]. The average age of the staff of Colleges of Advanced Technology is, as a consequence, at the moment probably the youngest for any period in their history and younger than they are likely to be at any future date. This has its positive side; such people are, in most cases, approaching their peak in initiative and creative ability. Their contact with industry is fresh and the system of organization, particularly in sandwich courses, enables them to keep it so.

On the other hand, the recruitment of senior staff, whose salaries and conditions, as Prof. Irving has noted, lag behind those in other professions and industries, has naturally proved difficult. It is not surprising that there are no Fellows of the Royal Society at the Colleges of Advanced Technology, where, until recently, there has not been a single position with a salary equal to that of a university professor in science and technology. Neither are the Colleges likely at the moment to attract into their own leading positions people who have, say, held research managerships or are at director level on the management side in important industries. Clearly they need to do all of these things. The young staff they have are the ultimate guarantee of the future, but, in the meantime, as the size of departments grows, there is a pressing need for a more mature leadership. Heads of department are extremely hard-pressed at the moment; there needs to be a rapidly developed multiple professoriate in each department in order that the burden of initiative and leadership can be appropriately distributed. This is partly a problem of raising the material prospects at the higher level in the Colleges, bearing in mind that the quality of leadership they need is not merely of academic distinction, but, in many cases, of proved ability to manage and lead large enterprises. However, whatever the attractions, it is neither possible, nor even desirable, that all the people who can make a major contribution from industry should have to leave industry to do so.

The Colleges will need arrangements that permit extra-mural appointments of the highest level. Already some of these have been provided in the individual Colleges in the form of industrial consultant lecturers. However, it needs the establishment of extra-mural professors with a full status in the Colleges, as well as in industry, including a participation in the policy decisions of both, to secure the contribution which is really needed. The contribution of such people needs to be distinguished sharply from the older contribution of part-time lecturers, which is likely, if anything, to diminish rather than increase as evening classes disappear. The part-time lecturer, although giving valuable service, was not sufficiently an organic part of the College for which he worked. He rarely saw the whole picture, and his contribution was minimized by the fact that it consisted only of teaching. Unless the industrial technologists can be drawn into the policy-making, the planning and carrying out of research, into staff colloquia and seminars, as well as into the teaching of undergraduate and postgraduate students, they cannot form an integral and co-ordinated part of the life of the Colleges. This poses entirely new problems for co-operation with industry, problems which must be faced if we are to optimize the use of our most talented scientists and technologists, whether their main pre-occupation is in College or industry. It need scarcely be said that, reciprocally, there is needed an extension of the consultative and other methods by which College staff are drawn into the life and work, particularly research, of industrial units. These problems will tend to emphasise the regional significance of the Colleges, since such close co-operation will tend to take place predominantly on a regional scale. Nevertheless, there will be certain industrial connexions for each College which will tend to be of a national character, for example, metallurgy in the case of Birmingham College of Advanced Technology, material science, including fibre science, at Bradford, computer technology at Northampton College of Advanced Technology, production engineering at Loughborough, and mechanical engineering at Salford.

The industrial influence of the Colleges is particularly important in the case of research and postgraduate courses. Research has two significances for any college of higher education; first, to train research workers and, second, to provide a staff who are advancing the knowledge of the subjects they teach. For both these purposes it is

proper that research in Colleges of Advanced Technology should frequently be in close co-operation with research in industry. The Membership of the College of Technologists, devised by the N.C.T.A., has already set a new pattern for the training of the postgraduate research student, in which part of his work must be undertaken either within industry or under industrial supervision. More generally, the research in the Colleges of Advanced Technology is already tending to take the form of group rather than individual projects, with the concept of building up viable teams of workers for defined areas of research. Such a structure is making possible a closer alignment of the research of the Colleges with industrial needs. Undoubtedly, the major problem inhibiting all research in the Colleges at the moment, however, is the absence of a suitable higher award, to which reference will be made later. The same inhibition affects the development of postgraduate courses, which are another feature in which the closest co-operation with industry is desirable. The number of individual postgraduate courses is probably at present multiplying more rapidly than any other feature of the Colleges of Advanced Technology. While many of these are of a part-time character or of a relatively short full-time duration, they are a means of drawing into close co-operation people of the highest level in industry.

Of particular importance from the point of view of regional influence is the prosecution of management studies at postgraduate-level. Here we are dealing with a new discipline, about which, although there is a very widespread concern for its extension, there is considerable controversy concerning its nature and method. One thing which is reasonably certain is that at this stage it is almost impossible to disentangle the education of the manager from the management situation itself. This means that management studies are or should be an outstanding example of the close interaction between industry, business and college, about which we have been speaking. In this field, above all, it would seem necessary for the College and senior industrial staff to co-operate in producing an educational component to the whole preparation of managers, whether this takes place in industry or in College. It follows that this demands a strong regional influence by the College and its capacity to engage the direct co-operation of significant industrial enterprises. The importance of this is to be seen in contrast with the concept that the solution of our management education problems is to create a sort of national superschool of management on the lines of the Harvard School of Business Studies. The danger of this approach is that it could denude the growing points in the main industrial regions, whether in universities or Colleges of Advanced Technology, of their leading staff, and could postpone the close interaction of industry and College essential to success. Naturally it is necessary that the industrial co-operation should be supported in this field by strong College departments with an adequate backing of research: such examples as the work of Jahoda at Brunel and the school of research under Lupton at Birmingham have been points of initiative that have now been repeated in several other Colleges of Advanced Technology. In concluding this brief reference to the regional influence of the Colleges of Advanced Technology attention should be directed to the question of their relation to the next strata of colleges, the Regional Colleges of Technology. There are some 24 of these colleges, each of which undertakes a proportion of university-level work; they share between them the remaining 25 per cent of the Diploma in Technology students. A pressing question is the future of this work when the Colleges of Advanced Technology are given the power to grant their own degrees and hence withdraw from the ægis of the N.C.T.A. It seems desirable that future administration should permit the closest links between the Colleges of Advanced Technology and the Regional Colleges near to them. This could be obtained by a system of affiliation in which work in Regional Colleges would receive recognition in part or in full for awards under the overall academic supervision of the College of Advanced Technology.

The concept of a university is sometimes taken to involve a more or less complete coverage of all departments of human knowledge and research. For any single institution of education in the modern world such an objective is illusory. Nevertheless, the close link between the Colleges of Advanced Technology and industry compels them to widen their range of studies far beyond the purely technological or vocational. Such a range includes fundamental science in all its main branches, the social sciences and applied science and engineering. Indeed, it includes any subject which can be studied in the context of its possible application. There has always been a strong stream of the fundamental physical and biological sciences in certain of the Colleges. For example, Chelsea has developed strong schools in biochemistry and physiology, Salford and Battersea in chemistry, Bradford in polymer science. More recent has been the growth in all the Colleges to a greater or lesser extent of departments or schools of social science. At the undergraduate-level these are developing partly by the cultivation of traditional disciplines such as economics and partly by the devising of new courses, such as the sandwich Diploma in Sociology at Bristol, which lays emphasis on the sociology of an industrial society. New methods of studying languages in the context of problems of communication in the modern technological world are planned in some Colleges, while the Welsh College is unique in having a postgraduate diploma in the teaching of English as a foreign language. Brunel College is pioneering a sandwich course in industrial psychology, and Loughborough College is experimenting on a new synthesis of engineering and social science. Most Colleges are seriously considering the introduction of departments of education, partly because of the outstanding need to introduce a stream of teachers with industrial and technological experience, and partly in order to prosecute research into their own objectives, the nature of higher technological education itself. Both Birmingham and Brunel have pioneered in this field with research on the educational problems arising in sandwich courses.

Apart from this necessary extension of the overall range of interests of the Colleges, two developing concepts of the breadth of higher education and research are cardinal to their work. The first concerns the balance between specialization and breadth in the undergraduate course. Here the Colleges are tending to develop what might be called a concentric rather than a parallelistic approach to the problem of broadening the education of the specialist. This approach recognizes that development in depth, specialization to the point of independent work, is inescapable and desirable, but that fertile specialization in technology interacts organically, not merely with contiguous sciences, but with the social background in which it operates. Stated simply, this is not an attempt to add a gloss of wider culture to the technologist, but to develop in him a sense of his own contribution to society and its culture. This is why general and social studies are regarded as an integral part of his education as a specialist. This attempt calls for a high degree of interpenetration of departmental interests on the part of the staff and may lead to an abandoning of the rigid departmental structure in favour of organizing as teams all teachers who contribute to the education of a particular stream of undergraduates. The second development, which is at a still more nascent stage, is the creation of inter-disciplinary teams for research and postgraduate instruction. The tendency for research in the Colleges to become objective-based again breaks down departmental barriers and may require a new form of organization with the necessary flexibility to assemble and re-allocate research effort in the direction shown to be most fruitful. Examples of these beginning

are the formation of teams on such subjects as powder technology and materials science at Bradford, engineering design at Bristol, computer technology at Northampton, metal deformation and high-temperature technology at Birmingham.

This brief study of the Colleges has been bound to emphasize the general features that they have in common and to neglect their diversity of interests. Inevitably, no single pattern will obtain in the future, and even the problems that they have in common will probably permit several different solutions and organizational forms. However, the very fact that to some extent the Colleges are all deliberately orientated to the production of people who will solve practical problems and create new industries leads one to believe that they must develop a highly integrated approach in their philosophy of education, corresponding to the complex interaction of science and practice in the industrial world. It follows that, to fulfil this function, the Colleges cannot be small colleges; they must be large enough to include creative workers in the many disciplines that must interact in modern industrial technology. The actual size of an individual College will depend on the range of applied sciences and technologies, including the social sciences, that it includes: no College can contain the whole range; but it is necessary that each should contain a range sufficiently broad to be reasonably viable as a self-evolving unit. The Colleges' own preliminary estimate of the minimum immediate target to make this possible would provide for the education of some 40,000 full-time students, distributed in units of between 3,000 and 6,000 among the ten existing Colleges. It seems probable that in the light of more mature reflexion these figures will have to be revised upwards. As Prof. Bowden has pointed out, a typical Continental or American college of technology frequently contains 10,000 students. Naturally it is the number of staff in each complex of specialists that is critical rather than the number of students, which indeed can be calculated from some overall staff-student ratio, although this latter is clearly subject to modification in the light of more economical methods of teaching that may result from research in this subject.

The method of organization of these large units of science and technology poses some interesting problems. As mentioned already, it is likely that several Colleges will experiment in new forms of organization which involve the breaking down of departmental barriers and the creation of a much smaller number of large schools, each with a multiple professoriate and other staff, with directors of studies responsible for the whole team concerned with an undergraduate or postgraduate course, and with inter-disciplinary research teams flexible enough to be formed and re-formed according to the fertile growth of the research concerned. In some centres, such as Birmingham, considerable thought has been given to a system of federated colleges. Such a federation might include a college of technology and science, a college of commerce, a school of education, a college of industrial fine arts and a college of architecture and building.

The foregoing considerations refer to the organization of staff and facilities: the planning of the student community poses another set of problems, some of which are common to all institutions of higher education. However, the stress that Lord Fleck and many other leading industrialists have laid on the all-round development of the student as a future leader of industry makes the provision of residential accommodation, preferably on the campus, a key question for the Colleges of Advanced Technology. In this connexion, the development of the student village at Loughborough is being carefully studied, although other solutions will probably be necessary on urban sites. The main problem here is not that of imposing some kind of ready-made ethos or even moral outlook on the coming generations of students, who might indeed, with some reason, question the capacity or qualifications of the academic staff to undertake such a role; it is rather to create a new kind of community which, while on the campus, is open to the maximum opportunities for self-education, including the undertaking of responsibility, the formation of values and purposes, but, in another sense, is an open community in that a large proportion of the students, during their periods of industrial experience, will be deliberately breaking away from time to time from the college atmosphere and immersing themselves in the world of industry and commerce.

As mentioned at the beginning, this article is being written immediately before the Robbins Committee report. If, nevertheless, the venture that has been outlined is considered to be soundly based, it is necessary to consider what are the pre-conditions for its development and success. Five of these are of sufficient importance to be mentioned briefly.

The first is that, although the Colleges are to some extent committed to educating a man who will serve industry, and although they form an open community with a considerable interpenetration of industrial staff and influence, nevertheless they need, above all, the full autonomy associated with a university if they are to formulate and solve the many complex problems both of an academic and organizational nature that their purposes impose on them. The question of the issue of degrees both of a first and higher nature, including the doctorate, is not therefore merely a question of status: it is a vital organizational pre-requisite to the bold educational experimentation that must be undertaken in this field of higher technological education. This is particularly true in the case of higher degrees such as the doctorate. The doctorate is not only a national but an international symbol of maturity in research and creative work. The Colleges must be able to grant their own doctorates to attract and retain the outstanding leaders of research and the students of ability who are necessary to develop these fields in a fruitful way.

The material pre-requisites are the second pre-condition, and these are likely to be expensive, since science and technology are inevitably the most expensive to study and research. There has been a continuous underestimation nationally of worth-while expenditure in this field, both in universities and in other forms of higher education. It is thought in some quarters that the starving of university finance has been compensated by the lavish treatment of the Colleges of Advanced Technology. It is paradoxically true that, while under the local authorities, they were in fact generously treated, although their demands for capital equipment on the largest scale were somewhat limited by the restrictions on the research already noted. It must be stated that their first year under the direct finance status of the Ministry of Education has brought many of them disappointments in their plans for the immediate expansion of their material facilities. It would be unkind and perhaps unjustified to judge the future by the experience of this first year, which may have resulted from the problems involved in estimating a new venture, and there are signs that the scope of capital equipment required is now receiving attention, for example, in the plans to equip the Northampton College of Advanced Technology with a computer centre costing about £250,000. Whatever Minister is to be responsible for the future direction of higher education, must, so far as science and technology are concerned, be served by a body which can represent to him with the highest authority the proper and adequate allocation of funds for the development of the highest level of technological education and research.

The third pre-condition for success is the expanded co-operation with industry, and these aspects have been touched on already. Paradoxically again, this co-operation, although intrinsically between individual firms and the Colleges, may well depend on the creation

of new overall mechanisms for apportioning nationally the cost of industrial training and large-scale research projects. This is particularly true if co-operation is to be extended with the medium- and smaller-sized firms, the finances of which will not permit an altruistic attitude towards their profit and loss accounts. The fourth prerequisite is the recruitment of staff, both of the quality and in the quantity required. In order to reach the target of 40,000 students, we may estimate that an additional 3,500 teachers are required. A proportion of these need to be men of very great ability either drawn from industry or sharing their activities between industry and College. Some of these will inevitably be in short supply in the initial period until their work in industry can be supplemented by the new supply of people coming from the Colleges. Nevertheless, the financial factors, particularly salaries and facilities for research, must be faced realistically. The point is that if the top staff of Colleges of Advanced Technology are to be responsible for training future leaders of industry, they must themselves be men of the highest calibre. The fifth condition for sucess has already been dealt with to some extent when we were considering the problems of entrants and selection. It is that of co-operation with the schools. During the past few years this has developed to an unprecedented extent and a good many of the barriers of misunderstanding have begun to be broken down. In one College, for example, the staff make perhaps something like one hundred visits per year to the schools in the region, and several thousands of school boys and girls come in contact with the College. Increasingly, the staff at the schools are visiting the Colleges, taking part in symposia and conferences and special courses, and are beginning to appreciate something of the requirements and objectives. Nevertheless, it remains, from the long term point of view, highly desirable, if an adequate stream of our talented young people are to find their places in the Colleges of Advanced Technology as well as in university departments of applied science and technology, that new methods of teaching science should be experimented with and that a stream of industrially experienced teachers should find their way into the schools.

After a long induction period, higher technological education in Britain, through the medium of the Colleges of Advanced Technology, has taken the initiative in a new experiment, the construction of a fully viable and self-supporting spectrum of study and research, deliberately harnessed to supplying industrial and social needs. The impetus of their designation has carried them forward with a rate of expansion creating many problems demanding complete re-appraisal of our whole philosophy of scientific and technological education. Much of their work carries the inevitable marks of haste and improvisation. It is now essential that the administrative and organizational measures necessary for them to develop autonomously and with full momentum should be put into operation without delay.

OBITUARIES

Prof. J. J. Sudborough

Dr. John Joseph Sudborough died at his home in Torquay on July 25 at the age of ninety-three.

Born in Birmingham in 1869, he was educated at the Camp Hill Grammar School and in 1886 entered Mason's College with School and Entrance scholarships. He studied mainly under Profs. Tilden and Lapworth and graduated B.Sc.(London) in 1889 with double first-class honours in chemistry and geology.

Two years research work under Prof. Tilden followed, the subject being the additive reactions of nitrosyl chloride with olefines. In 1891 he obtained one of the first scholarships offered by the Commissioners of the 1851 Exhibition and proceeded to the University of Heidelberg, where he worked under Prof. Victor Meyer on stilbene derivatives. He graduated Ph.D. in 1893 and continued for a further year as private assistant to Victor Meyer, working on the subject of 'steric hindrance' as shown by diortho-substituted benzoic acids.

Returning to Britain, he worked for a period at Owens College, Manchester, and obtained a D.Sc.(London) degree. He was then appointed lecturer in organic chemistry at University College, Nottingham, under Profs. Clowes and Kipping, and there continued research, with student assistance, on 'steric hindrance' and on the additive compounds of trinitro-derivatives of benzene.

In 1901 he succeeded Dr. Lloyd Snape as professor of chemistry at University College of Wales, Aberystwyth. It was a time of great activity in Wales, for the University had been established in 1896 and the new intermediate schools were sending their matriculated pupils to the Colleges. Sudborough quickly realized his opportunity, organized an honours degree course and a research school and secured increased accommodation for his rapidly expanding department. A few years later, the generosity of Mr. David Davies (afterwards Lord Davies) and his Llandinam family enabled the College, in 1907, to erect the Edward Davies Memorial Laboratories, the equipment of which the professor supervised with meticulous care and of which he became the first director. During his decade of service at Aberystwyth, Sudborough taught and trained in research many men who later occupied important positions in the scientific world. He also took a leading part in College administration, served as dean of the Faculty of Science and as an officer in the Officers' Training Corps Contingent.

In 1911, after the death of his wife, he accepted the appointment as professor of organic chemistry at the Indian Institute of Science, Bangalore. Here, in association with the director, Dr. M. W. Travers, he inaugurated the work of the Chemistry Departments and developed a sound and thorough system of training in organic chemistry. In 1914 Dr. Travers retired, and Sudborough became head of the Departments of General and Organic Chemistry with Dr. H. E. Watson as assistant professor. Their output of papers, many of technical importance, was afterwards considerable.

After retirement in 1926 he lived at Ermington, South Devon, where he took much interest in local affairs and served on the Plympton Rural District Council. Later, moving to Torquay, he became honorary secretary for many years of the Torquay Natural History Society. He became a life governor of the University College of Wales and served for many years on its Council.

He was twice married, first to Miss J. Hunter, of Belfast, and secondly to Miss Elsie Bean, daughter of Mr. A. Bean, sometime postmaster-general of the Punjab, who survives him. He leaves no children.

T. Campbell James

Dr. B. Lambert, O.B.E.

Dr. Bertram Lambert died on July 1, aged eighty one. For half a century, as undergraduate, demonstrator

and finally as administrative head, he was associated with the laboratory first called the Chemistry Department, University Museum, Oxford, then the Old Chemistry Department, and later the Inorganic Chemistry Laboratory. He went up to Oxford from Giggleswick School as exhibitioner at Merton College, and obtained a first class in chemistry in the Final Honours School of 1903. The head of the Department, Prof. Odling, appointed him to the small body of demonstrators whose duties were to lecture and to teach, but with no encouragement or example towards research. Lambert, however, as an undergraduate had received a taste of the new physical chemical methods of measurement which had just been introduced from Ostwald's Laboratory in Germany into the undergraduate course at the Daubeny Laboratory belonging to Magdalen College. Single-handed he began to prepare himself for original work, which in those days was concentrated on the development of techniques for achieving the highest accuracy of physical measurements on chemical substances. Everything needed to be done the hard way. By intensive and methodical late-night practice, Lambert made himself equal to a professional in glass-blowing, and highly skilled in the laboratory arts of apparatus construction. Having no technical assistance, he made his own vacuum pumps, traps, manometers, internal heating devices, and often his own taps (all, in early days, of soda glass). This manipulative skill culminated in the construction of a quartz microbalance for the measurement of gaseous densities (*Phil. Trans. Roy. Soc.*, 1950), whereby the atomic weights of carbon and nitrogen were determined with an accuracy of 5 parts in 10^5.

His first published work related to the rusting of iron, and involved lengthy experiments on the preparation of highly purified water, oxygen and iron, from which he concluded that the rusting process was essentially of an electrolytic nature, a view which was only to find general acceptance many years later. After the First World War, he took up the study of adsorption of gases with a long series of carefully planned experiments on the palladium–hydrogen system and on the equilibria of vapours and gases with ferric-oxide and silica gels. This work brought out the difficulties of the subject associated with hysteresis effects. A paper published in 1939 showed how, by the most careful attention to detail, chemical methods of gas analysis could be brought to an accuracy of 0·02 per cent on a total volume of only 10 c.c. During all this work he was continually perfecting matters of technique and methods of achieving the highest purity of the gases used; particular reference may be made to his preparation of pure nitrogen. The elaborate care he constantly took meant that his output of publications was not large; his involvement in the planning and technique of measurement often seemed to exceed his interest in the significance of the results. His sound instruction in method, however, was invaluable to students who worked under his supervision.

Dr. Lambert is perhaps best known for his initiative in the First World War towards the production of respirators. Immediately after the first gas attack, the Army set up a defence organization under Col. Horrocks, assisted by Col. Harrison and Major Sadd, and early trials were made of respirators of impregnated cloth of Balaclava helmet shape. As early as June 1915 Lambert, while on leave from the Royal Engineers, himself constructed a box-type respirator with soda–lime–permanganate granules as absorbing agent. He took this to the War Office, and his principle was quickly recognized as superior to all other proposals. In the following year box-respirators with Lambert's granules, together with charcoal, were issued to the troops, and continued in use throughout the War. This contribution was recognized later by a substantial monetary award from a War Inventions Board of scientists and by an O.B.E. from the Government.

As soon as the First World War was over, Lambert returned to Oxford and was elected Fellow of Merton College. Additional responsibilities came easily to him. Besides carrying a full load of tutorial teaching, laboratory demonstration and research, he was called on to act as mediator and peace-maker in disagreements during the early part of Prof. Soddy's tenure of the chair. When Soddy retired he effectively administered the Inorganic Chemical Laboratory until his own retirement in 1947. He was active in all affairs and committees relating to chemistry at Oxford, and served helpfully as a member of the University Chest during the Second World War.

Lambert possessed the virtues of a true Yorkshireman: cheerfulness, sociability, self-reliance, moderation, appreciation of honest, hard work, and wise judgment of men and things. He enjoyed playing cricket when young, and bowls and golf in later years. His marriage to Sylvia Dewe in 1908 was a happy one; she survives him. His daughter, Peggy, is married to Group Captain Peter Broad, and his son, James Dewe Lambert, is Fellow of Trinity College and University lecturer in chemistry at Oxford.

E. J. Bowen

NEWS and VIEWS

The University of Strathclyde

It has recently been announced that the Royal College of Science and Technology, Glasgow, has received its charter as the fifth university in Scotland. This important development in university education in Scotland was described by Dr. S. C. Curran, principal of the College, in *Nature* of August 31, p. 843. It has now been announced that the new name of the Royal College is to be University of Strathclyde. Lord Todd, professor of organic chemistry in the University of Cambridge, has been elected the first chancellor. Dr. Curran is to be the first principal and vice-chancellor. The University of Strathclyde will naturally devote itself to the advancement of learning mainly through the fundamental and applied sciences. Unlike the other four universities in Scotland it will not have a Rector.

U.S. Air Force Office of Scientific Research : Dr. W. J. Price

Dr. William J. Price, former chief scientist of the Aerospace Research Laboratories, Wright–Patterson Air Force Base, Ohio, has been appointed executive director of the U.S. Air Force Office of Scientific Research, Washington. The Air Force Office of Scientific Research is responsible for the administration of grant and contract awards to industry, universities and other institutions whose proposals for research projects have been selected by the Air Force for support. Dr. Price was chief of the Modern Physics Research Branch at the Aerospace Research Laboratories prior to becoming chief scientist there in 1959. Since receiving his Doctorate in Physics from Rensselaer Polytechnic Institute in 1948, he has worked almost continuously for the Government. During 1949–54 he was associate professor of physics at the Air Force Institute of Technology (AFIT). In February 1954 he was appointed head of the Department of Physics there. He held this post until 1957, when he went to the Aerospace Research Laboratories as chief of the Modern Physics Research Branch.

The Finance of Education

The report of a conference on the finance of education, organized by the 1963 Campaign for Education, and

held on April 23, contains the text of the addresses of the two principal speakers, Sir William Alexander and Mr. J. Vaizey, together with a report of the discussion (*The Finance of Education*. Pp. ii+34. London: 1963. Campaign for Education, c/o Hamilton House, Mabledon Place, London, W.C.1, 1963. 2*s*. 6*d*.). Both speakers strongly urged a reduction in the number of education authorities from the present 146 to about 50, each with a population of about one million, but the discussions emphasized that there was no single answer to the problem of educational finance and that some of the proposals now being canvassed have disadvantages or dangers. Sir William Alexander pointed out that expenditure on education was increasing at the rate of about 9 per cent per annum and was already 4·9 per cent of the national product, while productivity was increasing by only about 2·5 per cent, and he did not think the present system could stand the strain of the next two decades. He thought a percentage grant system relating the contribution by the central Government directly to the expenditure that a local authority incurred on the education service was essential; however, he did not think that the financial problem could be considered by itself. Further, it was necessary to consider what was the highest proportion of the gross national product that Britain could invest in education without detriment to the national economy, and the total manpower she could invest in teaching without detriment to increased growth. Such fundamental questions required consideration by an independent commission. Mr. Vaizey suggested that these fundamental questions were more for consideration by the profession itself than by a Royal Commission, and he looked for the association of teachers with such developments just as the medical profession was associated with the National Health Service. While he welcomed the increased concern of the central Government with education and thought that the crucial question in the finance of education (in which higher education represented an increasing proportion) was the future of the rates as an educational tax, he stressed the importance of regional bodies. Prof. Bondi agreed as to the extent to which innovation and experiment came from the periphery, not from the centre.

Educational Statistics for Britain

The second volume of the educational statistics for 1962 has recently been published by the Ministry of Education (*Statistics of Education*, Part 2, 1962. Pp. 115. London: H.M.S.O., 1963. 20*s*. net). The topics dealt with include General Certificate of Education examinations, further education and teacher training (excluding, however, the universities), scholarships and awards, the school health service, school meals and milk, and educational building. As regards Advanced Level examinations for the General Certificate of Education, it is interesting to note the increasing number of candidates offering economics at that examination. During the past decade the number has increased from about 900 to 5,000. There are also considerable increases in the number of candidates passing science and mathematics; the number of girls passing these subjects has increased faster than the number of boys, but the disproportion still remains very great, except in the biological sciences. In the science group, mathematics passes have increased most in the past decade, and passes in the biological sciences least. The further education section contains figures on the colleges of advanced technology, containing 4,800 students on full-time, and a further 6,200 on sandwich courses. The statistics on students completing teacher training in 1961–62 are affected by the introduction of the three-year course in training colleges; of 7,700 qualifying in that year 3,400 were graduates, a figure which has not changed significantly during the past three years. The section on awards makes it possible to obtain some idea of the wastage rate of university students; of the local authority award holders 13·3 per cent of the men and 12 per cent of the women were classed as premature terminations, and a further 4·9 per cent of the men and 4·0 per cent of the women failed their final examination, thus indicating that just less than one in five of undergraduate award holders fails to complete his or her course satisfactorily.

Scientific Research in British Universities and Colleges, 1962–63

The 1963 edition of *Scientific Research in British Universities and Colleges* contains brief notes on scientific research in progress in British universities and colleges, and describes the nature of the projects in sufficient detail to indicate the scope of the research done by the various science departments and individual teams of investigators. The social sciences and industrial administration are not included except where work in these fields normally occurs within the science faculty or technology department. Information is supplied for 76 university colleges, institutes and medical schools, and 48 colleges of technology. Each university, college, etc., is divided up under subject headings giving staff, their qualifications and fields of research. A name index and a subject index are provided, also a list of addresses of the various universities and colleges, including telephone numbers. Immediate reference to any name or aspect of research is given by means of a duplex code system. The publication is sponsored by the Department of Scientific and Industrial Research under an arrangement with the British Council (1962–63. Pp. xxvi+670. London: H.M.S.O., 1963. 32*s*. 6*d*. net).

The Belgian University Foundation

The forty-second annual report of the Belgian University Foundation covering the year ended September 30, 1962, records twenty-four grants to postgraduate students during the year totalling 590,000 francs, subsidies to publications of some 2·8 million francs, of which 2·3 million francs were for periodical publications, and grants to scientific societies totalling 896,000 francs (Pp. 152. Brussels: Fondation Universitaire, 1963). It includes also the twenty-third annual report of its Bureau of Statistics, which gives the number of students in 1961–62 as 32,726, of whom 19·7 per cent were women. The largest number of students were in the University of Louvain, and 13·47 per cent of the total were in science, 25·16 per cent in medicine, pharmacy and related fields, 12·16 per cent in applied science, 13·17 per cent in commercial science, and 6·01 per cent in social, political or economic science. The report also deals with the prizes awarded by the Foundation, conferences and reunions held under its auspices, the centre for scientific societies and documentation services which it supports, including an index of periodicals, and lists twenty-six fellowships awarded for 1962–63 by the Belgian American Educational Foundation, as well as of bursaries. Notes are included on the activities of the various other institutions with which the Foundation has particular relations.

The Journal of the Association of Public Analysts

Analysts, consultants and chemists employed in the food and drugs industries will welcome the appearance of the quarterly *Journal of the Association of Public Analysts* (1, No. 1. Pp. 1–24. London: Association of Public Analysts, 1963, Annual subscription, 30*s*.). It is intended that this new journal will include analytical and technical contributions, correspondence, reports on legal matters and the Association's views on food standards. The first issue includes the following papers: "Detection of Insecticide Residues in Fruit and Vegetables", by P. S. Hall; "Determination of Chlorinated Pesticide Residues", by J. A. Potter; "Differentiation of Canned Processed and Canned Garden Peas", by A. Houlbrooke; "Analytical Data for Grapefruit Juice", by J. G. Sherratt and

R. Sinar; and "Determination of the Almond Content of Marzipan", by H. E. Monk. Minimum standards of composition are quoted for sausages, luncheon meat, flavoured milk, marzipan and candied peel. These represent the official views of the Association in relation to selected foods for which no legal standards exist. Under the heading "Items of Interest", D. R. A. Davies discusses some of the newer types of 'bacteria-free' milk such as 'Uperised' (Swiss) and 'Palarized' (Danish) which do not possess the 'boiled' taste and brownish colour of conventionally produced sterilized milk, and keep for at least a month. In their preparation, superheated steam is incorporated into the preheated milk, but automatic control should ensure that the composition remains unchanged. Two samples of 'Palarized' milk examined by Davies gave freezing-point depressions of 0·536° and 0·534° C, and he reported on them as "genuine despite the possible addition of water as steam". The *Journal* should become a very useful medium for the exchange of ideas, technical information, compositional data and analytical methods in the fields of food, drugs and water. Workers who are not directly involved in public analyst's work are cordially invited to send in contributions for future issues.

Australian Journal of Soil Research

RESEARCH workers in Australia in the numerous branches of soil science have earned an international reputation for work of the highest quality, and it is gratifying that the Commonwealth Scientific and Industrial Research Organization, in collaboration with the Australian Academy of Science, has arranged to produce a new periodical *Australian Journal of Soil Research* (1, No. 1 (February, 1963). Pp. 1–128. Melbourne: Commonwealth Scientific and Industrial Research Organization, 1963. 10*s*. per issue). It is intended to provide a means of communicating advances in the examination of soils and soil-plant relationships, and will be published only as the accumulation of suitable contributions dictates. The first issue contains 12 papers dealing with such topics as flow properties, water movement, aluminium compounds, polyphenolic constituents in leaves, weathering of dolerite and examinations of the Riverine Plain, New South Wales, and of æolian materials in Victoria.

Radiobiological Dosimetry

Radiobiological Dosimetry is one of a series of five reports issued by the International Commission on Radiological Units and Measurements which deal with various aspects of radiation measurements, and which have replaced the single and complete statement of the recommendations of the International Commission on Radiological Units and Measurements previously issued every three years (United States Department of Commerce: National Bureau of Standards. Handbook No. 88. Pp. vii+26. Washington, D.C.: Government Printing Office, 1963. 25 cents). The subject-matter has grown so much and, in some cases, has become so specialized that a single volume is no longer practicable. The report deals with radiobiological dosimetry and considers methods of improving the accuracy and intercomparability of dose measurements in radiobiology. Many conflicting results reported in the radiobiological literature no doubt stem from faulty dosimetry; in some papers essential data concerning the radiation source were either omitted altogether or described inadequately. There should be no more excuse for this if radiobiologists read the report on *Radiobiological Dosimetry*, since it sets out in clear terms the basic principles of dosimetry in radiobiological experiments, lists different classes of irradiation, and ends up with examples of the form in which exposure arrangements should be reported for publication. An appendix to the report contains a very useful description of various radiation quantities and units, including those, like kerma, which have been introduced only recently.

Antibiotic Dips for Preserving Fish Fillets

CHLORTETRACYCLINE (CTC) and oxytetracycline (OTC) have been used for some years in Canada for prolonging the storage-life of fish. A few instances have been reported, however, where dipping in antibiotic solutions has been found to be ineffective in commercial practice. The difficulties encountered are discussed in Bulletin No. 138 of the Fisheries Research Board of Canada, entitled "*Problems in the Use of Antibiotic Dips for the Preservation of Fresh Atlantic Groundfish Fillets*", by C. H. Castell and J. Dale (Pp. vi+70. Ottawa: Queen's Printer, 1963. 1.30 dollars). The Bulletin discusses the use of CTC dips and stresses that antibiotics cannot be expected to be effective if applied to fish that are already spoiling or to apparently good fillets with a relatively high *p*H. Most of the bacteria found on fish are sensitive to CTC, and increasing the concentration of the antibiotic up to (but not necessarily beyond) 25–30 p.p.m. causes a corresponding extension of the storage life. Different fish tissues absorb the CTC from solution at different rates and its activity is gradually lost during prolonged storage. Various substances cause a decrease in the effectiveness of the CTC, namely, strong oxidizing agents, strong alkalis and certain metallic salts, so it is recommended that such compounds should not be present in dipping solutions. It is probable that the greatest single cause for decreased effectiveness of CTC in preserving fillets is alkalinity derived from dissolved solids in water, alkaline detergents and the developed alkalinity in the muscle itself. Fillets dipped commercially for 10 sec in solutions containing 10 p.p.m. of CTC were found to contain 0·1–0·6 p.p.m. (cf. legal maximum 5 p.p.m.).

Palæontology in the U.S.S.R.

THREE further volumes of *Principles of Palæontology* (*Osnovy Paleontologii*) have been published (*Nature*, 197, 854; 1963): (1) Mollusca: Cephalopoda I, Nautiloidea, Endoceratoidea, Actinoceratoidea, Bactriodea; Ammonoidea (Agoniatitidea, Goniatitidea, Clymeniidea), edited by V. E. Ruzhenzev, written by seven authors (Pp. 438+82 plates, 417 text-figs. 1962. Price 4 *r*. 35 *k*.). (2) Porifera, Archaeocyathidea, Coelenterata, Vermes, edited by B. S. Sokolov, written by 16 authors (Pp. 485+57 plates, 421 text-figs. 1962. Price 5 *r*. 7 *k*.). (3) Arthropoda; Trachaean, Chelicerata, edited by B. B. Rodendorf, written by ten authors (Pp. 560+22 plates, 1,535 text-figs. Price 4 *r*. 92 *k*.). *Principles of Palæontology* is produced by the Palæontological Institute, Moscow Academy of Sciences (Lenin Prospect, 33, Moscow B-71) in collaboration with a number of other institutes.

Simon Memorial Prize

THE 1963 Simon Memorial Prize has been awarded by the committee of the Low Temperature Group of the Institute of Physics and the Physical Society to Prof. H. E. Hall, professor of physics in the University of Manchester, and Prof. W. F. Vinen, professor of physics in the University of Birmingham, for their work on liquid helium II. The Prize of £250 will be presented by the president, Sir Alan Wilson, at the Royal Institution, London, on October 28, when the prizewinners will give short addresses on their work. Visitors will be welcome; tickets are not required.

The Ramsay Memorial Fellowship

THE Ramsay Memorial Fellowships Trustees have made the following awards of new fellowships in chemistry for the year 1963–64. A General (British) fellowship to Mr. C. D. Akon at University College, London; a Canadian fellowship to Dr. W. F. Reynolds at University College, London; a Japanese fellowship to Dr. Shiori Ishino at the University of Reading; a Netherlands fellowship to Mr. F. B. van Duijneveldt at the University of Sheffield; a New Zealand fellowship to Miss Margaret Kershaw at the University of Reading; Spanish fellowships to Dr.

J. A. Leal Ojeda at the University of Hull and Mr. Vicente Gonzalez Gonzalez at the Grassland Research Institute, Hurley; United States fellowships to Dr. P. O. Offenhartz at the University of Cambridge, Dr. Violet Simmons at the University of Oxford, and Dr. E. A. Thiele at the University of Cambridge. The following fellowships for the same year have been renewed: Mr. D. T. Dixon (New Zealand fellowship), at the University of Reading; Dr. D. Vazquez Martinez (Spanish fellowship), at the University of Cambridge.

The Beilby Medal and Prize, 1964

Awards from the Sir George Beilby Memorial Fund are made by the Administrators of the Fund, representing the Royal Institute of Chemistry, the Society of Chemical Industry and the Institute of Metals. Sir George Beilby was president of each of these three bodies, and they jointly sponsored the appeal for subscriptions whereby the Fund was raised as a memorial to him after his death in 1925. The Beilby Medal and Prize, which consists of a gold medal and a substantial sum of money, is specified as being "For Advancement in Science and Practice". Such an award is now being offered annually, but more than one may be made on the same occasion if there are several candidates of sufficiently outstanding merit. Thus, two awards were made in 1963, each carrying a prize of 100 guineas. The awards are made to British scientists in recognition of independent original work of exceptional merit, carried out continuously over a period of years and involving the development and application of scientific principles in any field related to the special interests of Sir George Beilby, namely chemical engineering, fuel technology or metallurgy, in their modern interpretations. The awards are intended as an encouragement to men and women (preferably under the age of 40) who have done distinguished work of practical significance in any of these fields. Awards for 1964 are shortly to come up for consideration. Outstanding work of the nature indicated may be brought to the notice of the Administrators, either by persons who desire to recommend the candidate or by the candidate himself, not later than December 31, by letter addressed to the Convener of the Administrators, Sir George Beilby Memorial Fund, the Royal Institute of Chemistry, 30 Russell Square, London, W.C.1.

The Perkin Centenary Trust: Awards

The Perkin Centenary Fellowship for 1963 has been awarded to Mr. N. S. Rao (India), who has been a post-graduate student at the University of Birmingham for the past year. The Fellowship will be tenable from October 1 in the Department of Chemistry, Imperial College of Science and Technology, London, where Mr. Rao will work under the supervision of Dr. T. S. West. Perkin Centenary Scholarships have been awarded to Mr. H. A. J. Butterworth (Ashton-under-Lyne), tenable at the Royal College of Advanced Technology, Salford, and to Mr. C. R. Laycock (Bradford), tenable at the Liverpool College of Technology. Mr. Butterworth and Mr. Laycock are laboratory assistants with the Clayton Aniline Co., Ltd., and the Technical Service Department of the General Industries Division of Allied Colloids (Manufacturing) Co., Ltd., respectively. The Perkin Centenary Trust was established as a memorial to the discovery in 1856 of the first important synthetic dyestuff, 'mauveine', by William Henry Perkin. The centenary of this event was acknowledged by celebrations held in London in 1956 and widely supported by many organizations having an interest in chemistry, including the Royal Society, the Chemical Society, the Society of Chemical Industry, the Society of Dyers and Colourists, the Royal Institute of Chemistry, and the Association of British Chemical Manufacturers.

Courses on Management

The wide variety of courses described in a brochure published by the Urwick Management Centre is a remarkable tribute to the way in which management education is developing in Britain. The courses include short seminars for top management, longer courses for potential managing directors and for heads of organization and methods departments, as well as a mixture of seminars and courses on various aspects of marketing and selling and on production planning and control. Among the more specialized courses are a series specially designed for the construction industries and a course specially designed to show the application of network analysis techniques to industrial and commercial problems. Scientists should be particularly interested in the courses and seminars dealing with the management of research. The content of each course and seminar is described in the brochure as well as the way the course or seminar is arranged. Full details of the Centre, which has been in existence for fifteen years, and receives annually some 700 executives, may be obtained from the Director, Urwick Management Centre, Baylis House, Slough, Bucks.

Second International Congress of Medical Photography and Cinematography

It has been found impracticable to organize the second International Congress of Medical Photography and Cinematography in Great Britain in the foreseeable future, owing to the fact that, apart from a few notable exceptions, the support which was expected from many quarters has not been forthcoming. However, it is hoped that it may be possible to organize a limited number of small international symposia on specific problems associated with photography, cinematography and television in the service of medicine. Further information can be obtained from Mr. K. Moreman, Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C.2.

Announcements

The Kamerlingh-Onnes Medal of the Netherlands Society for Cooling Technique has been awarded to Dr. Franklin Kidd and Mr. C. West for their work on the influence of temperature, moisture and composition of gases on the behaviour of fruit.

Dr. H. Lehmann has been appointed University biochemist to Addenbrooke's Hospital, Cambridge, as from November 1, and the Medical Research Council's Abnormal Hæmoglobin Research Unit, of which he is honorary director and which has been housed at St. Bartholomew's Hospital, London, will move with him to Cambridge.

The next award of the Meldola Medal, the gift of the Society of Maccabaeans, will be made early in 1964 to the chemist who, being a British subject and less than 30 years of age on December 31, 1963, shows the most promise as indicated by his or her published chemical work brought to the notice of the Council of the Royal Institute of Chemistry before December 31, 1963. Further information can be obtained from the President, the Royal Institute of Chemistry, 30 Russell Square, London, W.C.1, the envelope being marked "Meldola Medal".

A course of six lectures on "Recent Advances in Virology" will be held at the South-east Essex Technical College, Dagenham, on successive Thursdays commencing October 31. Further information can be obtained from the principal, Dr. F. Heathcoat, South-east Essex Technical College, Longbridge Road, Dagenham.

The Thomson Lecture of the Society of Instrument Technology will be delivered by Prof. Dennis Gabor at the Royal Institution on October 24. The subject of Prof. Gabor's Lecture will be "Technology, Life and Leisure". Admission is by ticket only, which can be obtained from the Secretary, Society of Instrument Technology, 20 Peel Street, London, W.8.

THE U.K. ATOMIC ENERGY AUTHORITY

THE accounts of the Atomic Energy Authority for the year ended March 31, 1962*, were issued last April, together with the report of the Comptroller and Auditor-General, Sir Edmund Compton. They are now included in the ninth annual report of the Authority for the year 1962–63†, which adds a further appendix comparing the 1962–63 grants and the 1963–64 estimates, which stand at £108,124,000 and £114,897,000 gross receipts—the latter bringing the net expenditure to £67,876,000 and £60,204,000, respectively. Of the gross total, salaries, etc., account for £43,185,000 and £42,198,000, respectively; research, development and design contracts with industry, universities, etc., for £4,881,000 and £4,612,000; contributions towards the International Atomic Energy Projects Dragon and Halden for £2,329,000 and £2,195,000; and grants to the National Institute for Research in Nuclear Science for £7,205,000 and £8,445,000, respectively.

While the form of the balance sheet for 1961–62 is substantially changed from previous presentations, as a result of some change in security requirements, and the published information has been expanded, the operating account is still withheld from publication on security grounds. General research in the year ended March 31, 1962, is put at £40,557,186, weapons research, excluding military contracts, at £8,263,215, and grants to the National Institute for Research in Nuclear Science at £5,278,470 and to international projects at £1,809,115. Moreover, in the Consolidated Civil Trading Account, which shows a net profit of £24,080, contributions to research and development appear at £591,423, compared with £632,153 in the previous year. Considering the prospective future income of the Authority for the civil use of nuclear energy, Sir Edmund notes that in 1957 the Authority concluded that the possibilities of the magnox reactor system, derived from the Calder Hall reactor, would be largely exhausted in the first stage of the nuclear power programme. Further development of the advanced gas-cooled reactor would permit higher operating temperatures and fuel ratings with consequent greater efficiency. The construction of such a prototype was approved in December 1957, and, when completed in 1962, this had cost about £9·7 million, while some £10 million capital and current expenditure had been incurred in the development and production of beryllium for canning the fuel elements—a method of canning later found to be unsatisfactory and abandoned in favour of stainless steel. Further expenditure will be incurred in developing the system to full commercial use, and Sir Edmund adds that the Electricity Boards are not committed to the adoption of this system and that the Authority's own view is that the adoption of a particular system by the Generating Boards in the United Kingdom or overseas should await the demonstration of its feasibility, safety and economics.

Expenditure on the development of magnox fuel elements for civil use is charged partly to the Exchequer as non-trading expenditure and partly to trading, and an item of £14,047,382 for major development projects, charged to the Exchequer, includes some expenditure on research and development in support of the nuclear power programme. 'Genetic' development, in which the basic designs of the reactor and its fuel are established, and the feasibility, reliability and economics of the system are demonstrated, is regarded by the Authority as forming part of its statutory obligation to undertake civil research and development. After commercial exploitation begins, the cost of development is regarded as part of the cost of production and charged in the Trading Account. As from April 1, 1962, expenditure on further development of magnox fuel elements became regarded as appropriate to the commercial exploitation phase and sales prices scheduled for the following five years.

In the Authority's annual report the percentage deployment of effort between reactor projects in terms of qualified scientists and engineers, excluding basic research, is now given as follows: advanced gas-cooled reactor, 23; steam-generating heavy water reactor, 15; fast reactor, 36; civil marine-propulsion reactor, 13; and high-temperature gas-cooled reactor, 13. Generation of electricity from the magnox reactors at Calder Hall and Chapelcross increased by 13 per cent, and the reactors of the Central Electricity Generating Board at Bradwell and Berkeley have started delivering to the grid, as did the advanced gas-cooled reactor at Windscale in February, while by March 31 the Dounreay fast reactor had generated 2·5 million kWh, of which 10 per cent had been exported to the grid. Nor was progress confined to the reactor field. During the year, the world's first two cobalt-60 industrial irradiation plants, designed specifically for sterilization of medical products, began continuous operation, one at Slough and the other at Edinburgh. Both were built under licence from the Authority following large-scale experiments at the Wantage Research Laboratory. On the other hand, with the meeting of the Government's requirements for enriched uranium for defence, it was decided to reduce the output of the diffusion plant at Capenhurst to the minimum level necessary to keep the plant in product; a substantial reduction of manpower at the factory had to be effected by the end of 1962. About 50 per cent of the redundant employees have found alternative employment inside or outside the Authority.

Of the expenditure in 1962–63 on the Authority's programme of civil research and development of £48 million, some £35 million was current expenditure and £13 million capital facilities. Of 2,825 graduates or professional scientists or engineers employed on the programme at March 31, 200 were working for other bodies on repayment; 1,880 were engaged on the reactor development programme and the reactor systems research, 470 on general research, 190 on plasma physics and fusion research, and 85 on isotopes research. Some account of the research on reactor systems, which includes nuclear data for reactor calculations, experimental measurements in reactor physics and heat transfer in reactors, as well as instrumentation, fuel materials, canning and structural materials, and moderators and coolants, is given in a separate chapter in the report.

The ninth report also includes chapters on general research, on plasma physics and fusion research, on nuclear weapons and test direction, on commercial operations and raw materials, on health and safety, on information services, and on the Authority's international relations and on staff. Reductions in manpower raised considerable problems and recruitment was on a much lower scale, but the lower number of graduate scientific and engineering recruits was broadly sufficient for the reduced need; in 1963 the reduction will be mainly on the engineering side, but some scientific entrants will be required. Critical

* Atomic Energy Authority Act, 1954. Accounts 1961–62: Balance Sheet of The United Kingdom Atomic Energy Authority as at 31 March, 1962, and Accounts for the year ended 31 March, 1962; together with the Report of the Comptroller and Auditor-General thereon. (House of Commons Paper No. 187.) Pp. 14. (London: H.M.S.O., 1963.) 1*s.* 6*d.* net.

† United Kingdom Atomic Energy Authority. Ninth Annual Report for the period 1st April, 1962–31st March, 1963. Pp. i x + 87 + 7 plates. (London: H.M.S.O., 1963.) 6*s.* 6*d.* net. (See also p. 1121 of this issue of *Nature*.)

appraisal of training methods continued, and the variety and scope of internal training was wide, with special emphasis on the training of industrial supervisors. At the Harwell Reactor School, which was attended by 522 students, of whom 26 were from overseas and 262 were Authority staff, two new courses for Authority staff were an extension course in reactor engineering and a course on applied mathematics for engineers; a course for university engineering staff and one for science masters were also held. At the Calder Operations School, where 711 people (213 from overseas) have now attended, standard courses were held for physicists and engineers, and a new course for lecturers at universities and technical colleges.

Some research is included in the Authority's health and safety programme, for example, measurements of radioactivity in air and in rain-water, the study of radiological protection, including the development of instruments for precise measurements of radiation dose-rates down to very low levels and the determination of plutonium in urine and in the body. There was a marked increase in the Authority's commercial activities. Sales of radioisotopes rose from £1·4 million in 1961–62 to £1·473 million, of graphite from £2·843 million to £3 million, and of reactor fuel from £9·6 million to £22·5 million. This year the chapter on general research discusses the programme as a whole, which, on the basic side, aims to supply fundamental scientific knowledge for future developments of nuclear energy, and also to supply the scientific understanding needed to solve problems arising during the rapid development of the present programme. Much of the general applied research programme is concerned with the interactions of neutrons and other radiations with matter on both the nuclear and atomic scale.

In nuclear chemistry, work continued on the determination, by both radiochemical and mass spectrometric methods, of the proportions of fission product atoms formed with various mass numbers in fission by low-energy neutrons. In theoretical physics, special attention was directed to investigations of the magnetic and electronic properties of transition metals and their alloys, the properties of defects and defect clusters in metals, and the scattering of neutron beams by liquids and solids. In the physics of the solid-state, the individual atomic contributions to the magnetization of ferromagnetic alloys were identified by neutron diffraction techniques, and the weak magnetic properties of vanadium–chromium alloys, in conjunction with other physical measurements, have established the validity of the band models of electronic structure of these alloys. Other research on radiation damage is now concentrated on elucidating the underlying atomic mechanisms, and at the Atomic Weapons Research Establishment the electrical properties of semiconductors are being exploited to provide a sensitive method for analysing mechanisms of radiation damage. A new variable energy cyclotron is being built at Harwell for general studies on the physical and chemical effects of radiation. Research continues on the physical metallurgy of uranium, plutonium and other metals of technical interest as well as on the physical and chemical properties of the oxides, carbides, nitrides and sulphides of fissile and fertile elements. Besides chemical engineering research in the role of bubbles in gas and solid movement, an extensive programme of research is being undertaken in electronics.

The Culham Laboratory programme remains concerned with stability studies on a wide range of plasma containment systems, including both pinch configurations and magnetic traps. *Zeta* remains the main toroidal pinch experiment, and has been modified to increase both the initial rate of rise of current in the discharge and the time during which the current is held constant after the initial rise. Besides the study of several linear pinch systems, three methods of injecting particles into a magnetic mirror trap are being studied. Effort has been devoted to the production of computer programmes for magnetohydrodynamic and electromagnetic problems, and a long-term programme of technological studies to support the laboratory's scientific programme has been established.

BIOLOGY OF RADIOIODINE

THE Hanford symposium on "The Biology of Radioiodine" was held in Richland, Washington, during July 17–19, under the joint sponsorship of the U.S. Atomic Energy Commission and the Hanford Laboratories of the General Electric Co. (contract No. *AT*(45–1)–1350 between the Atomic Energy Commission and the General Electric Co.). About 150 visiting scientists from Belgium, Canada, France, India, Japan, United Arab Republic, United Kingdom, West Germany and the United States joined more than 70 scientists of Hanford Laboratories for two and a half days of formal presentations and a tour of the facilities of the Laboratories.

Participants were welcomed to the sessions of the first day by Dr. H. A. Kornberg, manager of the Biology Laboratory of Hanford Laboratories. He noted that this symposium on radioiodine was the second in an annual series, the first having been held in May 1962, on the "Biology of the Transuranium Elements", under the general chairmanship of Dr. R. C. Thompson. The third symposium, to be held in the spring of 1964, will be concerned with the "Biology of Radioactive Particles and Gases" and will be under the general chairmanship of Dr. W. J. Bair.

The symposium was devoted to evaluating the nature, effects and control of radioiodine in the biosphere under the following four general categories:

(1) "Physical Origin and Dispersion of Radioiodine", which covered sources of environmental radioiodine in nuclear industrial operations, accidents and weapons tests, and the nature and form of iodine dispersed and potentially available to the biota.

(2) "Biological Disposition of Radioiodine", which concerned entry of iodine-131 into and passage through biological systems and included uptake of different radioisotopes of iodine by means of various routes of entry in several species of animals, including those in an aquatic environment.

(3) "Biological Effects of Radioiodine", which emphasized comparative early and late effects of single and prolonged exposure in young and adults of various species and included carcinogenic effects on the thyroid of iodine and X-irradiation.

(4) "Prophylactic and Therapeutic Measures for Radioiodine", covering protective measures to reduce the thyroid uptake of radioiodine or its effects on the thyroid.

Principal fields within these general categories were reviewed by authorities and each review paper was followed by brief reports of unpublished work from many laboratories. Only a few of the fifty papers are here summarized.

The session chairmen were Drs. S. A. Lough and H. D. Bruner of the U.S. Atomic Energy Commission, Dr. A. H. Wolff of the U.S. Public Health Service, Dr. B. M. Dobyns of the Cleveland Metropolitan General Hospital, Dr. E. E. Pochin of the University College Hospital Medical School, London, Dr. Stuart Lindsay of the San Francisco Medical

Center at the University of California, and Dr. C. L. Comar of Cornell University: Dr. Shields Warren was the honorary general chairman.

In a succinct "Statement of the Problem", Dr. H. D. Bruner (Division of Biology and Medicine of the U.S. Atomic Energy Commission) began the scientific sessions by giving a brief history of radioiodine and pointing out the problem areas of concern. Historically, he related, the thyroid was considered a radio-resistant organ, and not many years ago it had been assigned a permissive yearly dose of 30 rems. Following reports of increased thyroid tumour incidence in children as a consequence of exposure to X-irradiation early in life, the Federal Radiation Council recommended a decrease in annual exposure, concluding that a thyroid radiation dose from iodine-131 of 0·5 rem/year would call for some control measures. As a result, Dr. Bruner pointed out, a dose of 0·5 rem has thus become a limiting case for normal peacetime operation.

J. Z. Holland (Division of Biology and Medicine, U.S. Atomic Energy Commission) comprehensively reviewed the origin and disposition of radioiodine. He compared the relative biological significance of the several radioisotopes of iodine, concluding that even in cases of heavy environmental contamination with the shorter-lived radioiodines, the delays in the food chain would tend to reduce their relative importance, with the result that longer-lived iodine-131 is of unique importance. The availability of parent tellurium (of radioiodine isotopes) could conceivably modify this conclusion; however, data presented at the symposium indicated that tellurium-132–iodine-132 would not represent a significant hazard to man following a contamination event involving pastures grazed by cows, etc.

In his review, Mr. Holland pointed out that one may expect extreme irregularity in the distribution of iodine-131 following a release incident. This results from the interaction of its relatively high abundance and short half-life with the buoyant rise imparted by the releasing event and the atmospheric eddies and rain clouds acting over periods of a few hours to days. Additional complications are introduced by the behaviour of iodine precursors during releases and by the chemical behaviour of iodine. Mr. Holland pointed out that iodine reacts with many materials, including trace substances in the atmosphere, and that it is readily oxidized and reduced through a wide range of valence states. The only conclusion which could be drawn at the present time regarding the partitioning of iodine-131 between vapour and particulates, soluble and insoluble forms and among elemental, reduced and oxidized states is that none is clearly dominant over any great range of conditions. Of interest, too, was Holland's observation that after deposition iodine-131 apparently sublimes and may be re-cycled by means of the atmosphere. However, it was noted by work in two laboratories that up to 90 per cent of the iodine in old fall-out may be in the particulate form, but that the iodine could be quite easily leached, the majority being in the reduced state. Releases from separations plant stacks at Hanford Laboratories were observed to be mainly in a gaseous state for at least 25 miles. Measurements performed at Harwell of stable iodine in the atmosphere indicated most of it was also in a gaseous state.

Dr. L. Machta (U.S. Weather Bureau) concluded the first session by explaining that three meteorological mechanisms can probably explain all incidents of higher-than-normal iodine-131-levels in the Public Health Service milk surveillance network since September 1961: (1) low-altitude transport of debris from atmospheric and vented underground tests in Nevada; (2) subsidence within an anticyclone; (3) rainout of debris moving in the troposphere or even in the lower stratosphere.

Prof. M. Eisenbud (New York University) pointed out that although there have been about twenty years of large-scale experience with iodine-131, we do not, as yet, have the correct yardstick with which to estimate the dose that would be received by individuals in an environment where the air or water is contaminated with iodine-131. He predicted that direct measurements of the radio-iodine content of milk would be for some time the indicator of choice when it is necessary to appraise the public health significance of environmental contamination by iodine-131.

Two reports dealt with the problem of deposition of iodine on to plants from airborne iodine-131. In the first, Drs. Barry and Chamberlain (Atomic Energy of Canada and U.K. Atomic Energy Authority, Harwell, respectively) stated that the absorption of iodine-132 on to leaves of the broad bean is controlled by the rate of diffusion of the gas through stomata. They found that in dry air the rate of deposition was one-tenth or less that in humid air. Dr. F. P. Hungate *et al.* (Hanford Laboratories) observed distinctly greater deposition of freshly generated iodine-131 inside leaves as compared with less pure and more particulate-laden off-gas from a melted fuel element. Translocation to other plant parts was slight.

Dr. C. P. Straub and J. H. Fooks summarized some co-operative field investigations involving environmental factors that influenced level of iodine-131 in milk. Of special interest were the results of an investigation performed in co-operation with the St. Louis Health Department. They observed that less iodine-131 was found in the milk of cows grazing well-fertilized pastures.

Under the general subject of "Comparative Uptake of Iodine by Different Species", more than twenty papers were presented. In the area utilizing animals as biological monitors, the work reported extended from using rabbits around the National Reactor Testing Station in Idaho to observations in thyroids of North American deer in many locations and thyroids of pigs in Michigan. The use of the latter species was suggested because their thyroids always showed higher iodine-131 concentrations than the human or fœtal thyroids sampled. Substantial uptake of radioiodine by means of the skin was reported. It was noted by workers at Hanford Laboratories that thyroid uptake of iodine-131 after the application of a $Na^{131}I$ solution to either a clipped area of skin or to a hairless area of sheep was about a third that observed following oral or parenteral routes of administration.

Of interest to medical diagnostic laboratories was the report that thyroid metabolic techniques are feasible with small doses of 1–10 nc. iodine-131 using a method described by Dr. M. A. Van Dilla and M. J. Fulwyler (Los Alamos Scientific Laboratory).

A series of papers from the Institute of Industrial Medicine, New York University, included means for estimating the distribution of thyroid doses due to iodine-131 in an exposed population, the dose of iodine-131 to human thyroids in New York City from nuclear tests in 1962 (up to 40 mrads) and on thyroid weights of a large number of adults (they suggest a mean weight of 16·7 g, which is less than at present considered for the standard man, that is, 20 g).

In a review of several investigations, Dr. G. Gaffney (U.S. Public Health Service) reported, under the general topic of "Radioiodine in Man", that at Brookhaven Drs. S. Cohn and E. A. Gusmano could not detect iodine-131 in thyroids of new-born whose mothers had thyroid burdens up to 230 pc. and milk values up to 100 pc./qt. Work at Northeastern Radiological Health Laboratory by Drs. F. Visalli and A. S. Goldin indicated that in children ingestion was the principal mode of entry of iodine-131, and thyroid uptake of iodine-131 could be suppressed but not blocked in children by giving 0·5 mg of iodine-127/day. Moreover, he and his co-workers had found the vehicle of intake of iodine-131 from fall-out was fresh foods, principally milk. However, uptake in man and animals'

thyroids was similar whether the iodine-131 was in a water solution or in milk, according to Dr. C. L. Comar and co-workers at Cornell.

Dr. R. J. Garner reviewed the available information on the comparative early and late effects of single and prolonged exposure to radioiodine in young and adults of various animal species. He emphasized the work on the animals of economic importance, which included chiefly the sheep, pig and cow, and took special note of the work performed at Hanford Laboratories since 1950 and work at the Compton Research Station on cows by Garner and associates. Garner's review served to point out the radioresistance of the thyroid gland of the domestic animal, with doses in excess of 5,000 rads being required before any sign of damage can be expected to appear.

H. Hollister of the Division of Biology and Medicine discussed the problems of estimating the hazards from radioiodine following a nuclear attack. In his paper, Mr. Hollister defined hypothetical nuclear attack situations and considered how information on the deposition and intake of radioiodine would be used to arrive at an estimate of the exposure dose to man and to the effect on grazing animals. He pointed out that interpretable information is needed at dose-levels quite in contrast to those of usual concern for weapons testing and reactor accidents.

Dr. I. Doniach (London Hospital Medical College) then presented a comprehensive review of "The Effects, Including Carcinogenesis, of Iodine-131 and X-rays on the Thyroid of Experimental Animals". Results of various investigators show a similarity in biological action of X-rays and iodine-131 on the thyroid. In the measurement of four different effects, 1,000 rads from X-rays has a similar quantitative effect to a calculated mean dose of about 10,000 rads from iodine-131. This comparative effect was somewhat less than the twenty-fold greater effectiveness of X-rays compared with iodine-131 reported by Dr. R. O. McClellan and associates at Hanford Laboratories on the early changes seen with these two forms of exposure in sheep. Dr. S. Lindsay, in this same session, concluded that thyrotropic stimulation after sub-total thyroidectomy is a promoting factor in the development of both benign and malignant thyroid neoplasms in the rat and that it may also initiate the development of some malignant neoplasms. In an extension of these findings in animals, Dr. E. L. Saenger *et al.* presented a very complete analytical review of the available data on the carcinogenic effects of iodine-131 compared with X-irradiation in man. These workers concluded that thyroid carcinoma will only rarely develop with X-ray doses of 2,000–6,000 r. after a latent period of 10–35 years, and that it is probable that X-ray doses of 100 r. or greater to children's thyroids will increase the incidence of carcinoma. Irradiation of the adult thyroid with iodine-131 cannot as yet be implicated as a carcinoma-causing mechanism; however, doses of iodine-131 to children seem to increase the susceptibility of their thyroids to neoplastic change. Dr. Saenger stated that the carcinogenic dose-level for a child from iodine-131 would probably not be below 600 rads, considering the differing dose rate between iodine-131 and X-rays, fractionation of dose and irregular distribution.

In the only paper in the session devoted to carcinogenic effects of iodine-131 compared with X-irradiation in man, Drs. Dolphin and Beach (U.K. Atomic Energy Establishment, Harwell) reported on a survey of the literature which they had performed. They concluded that the latent period from tumour development appeared to be independent of the thyroid dose in the dose range considered ($< 40{,}000$ rads), but did show a fairly distinct bimodal response. They estimated a total thyroid tumour incidence of $3{\cdot}5/10^6$ people/rad.

Dr. F. W. Lengemann, in his review of "Prophylactic and Therapeutic Measures for Radioiodine Contamination", pointed out that the best policy is to prevent the entrance of iodine-131 into the food chain since this is apparently the major route of contamination for those not occupationally exposed. Because milk appears to be the chief vector of iodine-131 in the United States and some other countries, he proposed four means of limiting the access to the food chain by means of milk: (1) eliminate milk from the diet; (2) using ion-exchange columns to remove radioiodine; (3) feeding milk-producing animals with stored feed; (4) the substitution of fresh milk by stored milk or milk products. An added consideration was the use of thyroid-blocking agents at a number of places in the feed–milk–man cycle. The foregoing possibilities were expanded into an interesting discussion of some of the advantages and disadvantages of each.

Dr. W. J. Bair *et al.* (Hanford Laboratories) stated in their brief paper that the release of stable iodine simultaneously with a release of iodine-131 to reduce the thyroid uptake of iodine-131 is feasible on a biological basis, but that physical and chemical phenomena accompanying the release of iodine vapours must be considered in a final evaluation of this procedure as a method of decreasing the hazard of reactor-released iodine-131.

Dr. Stumpf, reporting on work performed with Prof. E. H. Graul *et al.* at the University of Marburg, proposed, on the basis of their investigations on elimination of iodine-131 that: (1) a combined treatment with thyroid-stimulating hormone and potassium perchlorate be used to give optimal results at time intervals exceeding 24 h after administration of iodine-131; (2) gastric lavage (with injection of potassium perchlorate) be used within the first few hours following exposure to iodine-131; (3) ingestion of salivary secretions be avoided.

In the final paper of the symposium, E. C. Watson (Hanford Laboratories), reporting on a co-operative endeavour, noted that increasing the cow's dietary intake of stable iodine to 2 g/day reduced uptake of iodine-131 by the thyroid of milk drinkers by 50–80 per cent. Other workers from Hanford Laboratories noted that by increasing the stable iodine content of the diet of the cow from 5 mg to 2 g/day, levels of iodine-131 in milk decreased by 50 per cent and the cow's thyroid burden was reduced by more than 90 per cent.

One of the highlights of the entire symposium was a very spirited, timely and thought-provoking banquet speech in which Prof. E. E. Pochin addressed the question: "What is a Permissible Dose ?" "Perhaps it is more reasonable to look at what is a permissible risk", he said, and went on to cite some interesting comparative levels of risk in established industries to-day, based on fatal accidents per year or per million people employed. Prof. Pochin stated that, although we still have a great deal to learn about quantitation of risks in radiation exposure, we have even further to go in attempting to estimate quantitatively the benefits that may be associated with any procedure involving radiation exposure. "In the equation between hazard and benefit", he stated, "it is silly to be tidy-minded about the left-hand side of the equation if we have no figures on the right-hand side with which to compare it. I am sure that more quantitative thinking is needed on the benefits as well as on the risks". Prof. Pochin went on to say that the attempt to set levels of radiation protection on the quantitative basis is very necessary, but a very ambitious one. Many of the difficulties and also criticisms arise simply from the fact that no comparable attempt is being made to deal as quantitatively with many of the other hazards of life or work. This, in fact, may be one of the greatest values of radiation protection work—it may extend the use of hazard evaluation into other fields and there promote development studies of the justification for risks on a factual basis.

Collectively, the papers presented at this symposium represented the present state of our developing knowledge and should promote proper evaluation of the hazards of radioiodine.

L. K. Bustad

THE ONTARIO RESEARCH FOUNDATION

THE annual report of the Ontario Research Foundation for 1962* includes the reports of the director, Dr. A. D. Misener, and the director of research, A. E. R. Westman, the financial statement, lists of scientific and technical papers published during the year and of research awards and details of staff and advisory committees, etc. Contract research for industry increased from 34 contracts, valued at some 522,000 dollars, in 1961, to 48, valued at 660,000 dollars, in 1962, largely as a result of the activities of the project development group. Reference is made to the new research community developing around the Foundation's new location west of Toronto. The Canadian Gas Association has now taken over responsibility for operating the gas appliance testing facilities set up and operated by the Foundation since 1956. Unsponsored research in the Department of Biochemistry was concerned with selectivity in hydrogenation and the molecular structure of fatty acids, and in a search for new antibiotics from insects two compounds were isolated, one being identified as a small peptide or protein, and the other as a substituted quinone. A microbiological examination showed that in the biological treatment of wastes and sewage no flocculation occurs if the bacterial cells are broken up.

In the Department of Chemistry, a kinetic study was made of reactions of active nitrogen with simple alcohols, and the structure and thermal stability of molecular complexes of urea with long-chain hydrocarbon derivatives and the mechanism of retardation in the setting of plaster of Paris were investigated. Research on phosphate glasses was concerned mainly with constitution studies by means of paper chromatography, and studies on nucleation and crystallization in metaphosphate glasses continued. Metal physics research in the Division of Engineering and Metallurgy included the fundamental investigation of ultrasonic-wave attenuation in elastically strained ferrous materials in an effort to correlate dislocation and domain movements with metal breakdown or fatigue. The investigation was extended to pure metals, such as iron, molybdenum, tantalum and niobium, and an investigation of the ductile-brittle phenomenon in Armco iron at low temperatures by ultrasonic methods was started, as well as an investigation of the iron–carbon–uranium alloy system. In the Ore Dressing Division, a 'flash roaster' was further developed, particular attention being directed to burner design, and several applications of ultrasonic energy were tentatively explored.

The Department of Parasitology continued its studies of parasites occurring in the mammals, birds and fish of Ontario, and an investigation of tapeworms of foxes and dogs suggested that infection with the larval stage of *Taenia crassiceps*, due to eating mice, results in resistance to infection, which is probably due to the production of certain types of white blood cells. The determination of the life-history of 'throat-bots' in deer was concluded and the research has demonstrated the production of two generations of flies each year and the slow growth of bots in the throat in winter. Radioactive phosphorus was used to measure the size of blood meal, frequency of feeding, longevity and flight range of black flies feeding on ducks. In the Department of Physics, application investigations of the atmospheric electron probe continued, experimental studies in vacuum technology continued, and work was completed on a new type of high-voltage heat-to-electricity converter. The Department of Physiography continued to extend its physiographic survey into Northern Ontario with the mapping of surface deposits in Muskoka, Parry Sound, and the main glacial features were detected by a transverse along the Canadian National Railway between Fossmill and Petawawa and by aeroplane flights over Algonquin Park. Field study of the effect of weather on corn growth and development continued on a reduced scale, and investigations on the influence of Lakes Erie and Huron on the Ontario climate also continued, and microclimatic investigations of light intensity within the crops, soil moisture, etc., for alfalfa and bromegrass. In the Textiles Department, work on the molecular cross-linking of cellulosic fibres to improve certain properties of cotton and viscose rayon fabrics, and on the elastic behaviour of wool and hair, have been resumed.

THE NATIONAL CHEMICAL LABORATORY

THE report of the National Chemical Laboratory, 1962, includes the reports of the Steering Committee and of the Director*; that of the Director includes accounts of the work of the six research groups and lists of publications during the year. The planned transition of the work of the Extraction of Metals Group from a programme entirely devoted to work for the Atomic Energy Authority to one of basic research as part of the Laboratory's own work proceeded smoothly. The Steering Committee considers that increased effort in chemical thermodynamics, particularly of inorganic substances, is needed, and that the Corrosion of Metals Group should be expanded to permit study of the corrosion problems of some of the important new metals such as vanadium, niobium and titanium, and also corrosion problems at high temperatures. It does not consider that the Laboratory should at present undertake research on fuel cells, unless requested to do so, under contract, by some other organization. It considers, however, that co-operative arrangements, such as that under which an industrial firm has seconded a member of its own staff to work in the Laboratory for three years on thermodynamic measurements of phosphorus compounds, should be strongly encouraged in view of the complex apparatus involved. It has been agreed that the Properties of Pure Materials Research Sub-Committee shall cease to exist as a joint sub-committee of the Laboratory and the National Physical Laboratory, but the sub-committee has been renamed the Chemical Thermodynamics Research Sub-Committee and will advise the Steering Committee on such work at the National Chemical Laboratory.

The Director's report directs special attention to the promise of the application of high-temperature flame technology by the Extraction of Metals Group in mineral processing, for example, to fuse and quench individual beryl particles with the minimum of interaction with accompanying gangue material and the virtual elimination of container material problems. The research sponsored by the Atomic Energy Authority in the same Group on

* Department of Scientific and Industrial Research. Report of the National Chemical Laboratory 1962: Report of the Steering Committee and Report of the Director of the National Chemical Laboratory for 1962. Pp. iv+91+4 plates. (London: H.M.S.O., 1963.) 6s. 6d. net; 1.30 dollars.

the extraction of uranium and the chemical processing of low-grade beryllium ores has been further curtailed and the effort devoted to fundamental problems in inorganic chemistry increased, while besides flame technology other new techniques like the rotary contractor for solvent extraction from pulps are being applied in a wider context. In the Inorganic Group, studies on the separation of the rare earths have now ceased, as have those on the ultra-purification of elements, and interest has now shifted to the solid-state chemistry of rare-earth compounds. The catalytic properties of europium are proving of interest, as are also the reflectance spectra of the rare earths, while the section set up to work on X-ray diffraction has been widely used and a new section created to deal with electrochemistry.

Considerable changes are taking place in the organic chemical work of the New Materials Group, where the work on boron–nitrogen polymers is being tapered off and comparable study of the less-known organo-aluminium–nitrogen compounds has led to the characterization of low-polymeric substances of a new type and unusual molecular structures. Progress is reported in the synthesis and study of organic semiconducting material and in the understanding of intermolecular electron-transfer processes. Work on the physical chemistry of ion-exchange has now permitted the relations between the selectivity of a resin, its degree of cross-linking and its exchange capacity to be framed in rather general terms, and these investigations, and those of the selectivity and transport process in ion-exchange membranes, are relevant both to technological applications of such materials and to an understanding of membrane phenomena, etc., in biological systems.

The Chemical Thermodynamics Programme has entered a highly productive phase, and during the coming year the responsibilities of the Group will be extended to include a more general concern with chemical physics. The Laboratory is equipped with both static and rotating bomb calorimeters, and besides measurements of the thermodynamic properties of organic oxygen compounds, measurements have been made on organic fluorine compounds to establish bond–energy relations and to provide highly accurate heats of combustion of substances which may be used as secondary standards in the combustion calorimetry of organo-fluorine compounds. Critical temperature measurements have been made on a further eighteen compounds, including twelve substituted phenols with critical temperatures between 420° and 460° C, and for the four butanols critical densities and pressures were also measured. An investigation of the thermodynamic properties of non-stoichiometric compounds has been started and a solid-state electrochemical cell constructed. A batch of *m*-ethylphenol with a purity of 99·91 moles per cent has been synthesized from acetophenone as well as highly purified samples of *p*-ethylphenol, diethyl ketone, 3-methyl-6-*t*.-butylphenol, methyl *n*-propyl ketone and 2 : 5-xylen-1-ol.

In the Corrosion of Metals Group, research on metallic corrosion remains a continuing theme and during the year has been concentrated on corrosion in flowing water; passivation or inhibition and the specific role of the anions in a corrosive solution; and anaerobic corrosion in soils and polluted waters. As well as fundamental studies, work on underground corrosion, essentially microbiological, has included a survey of the aggressiveness of soil at various sites in England and Wales and a continued long-term experiment on corrosion under conditions presented by the River Thames. Topics to which the Isotope Applications Unit has devoted much time to include the possible utilization of the Mössbauer effect for studying structural chemical problems, the labelling and pulverizing of coal, the distribution of activity along threads or wires and liquid scintillation counting. The Director's Research Unit has studied the interaction of oxygen with tungsten surfaces by electron microscopy and the accommodation of copper atoms evaporated into ultra-high vacuum on to a clean tungsten surface.

The staff in post at the end of the year included 54 scientific officers, 7 research fellows, 104 experimental officers, 29 scientific assistants, 2 works technical officers, 20 executive and clerical, and 44 industrial, the authorized complement being 286 compared with 293 at the end of 1961. No progress has been made in relieving the serious shortage of accommodation.

THE EMPLOYMENT OF CAMBRIDGE GRADUATES

THE results of a survey, *The Employment of Cambridge Graduates**, made by Mrs. Christine Craig to help the University of Cambridge Appointments Boards, has been published by the Cambridge University Press. It covers the present occupation of Cambridge graduates of 1952 and 1953, the levels of responsibility and the salaries they have attained, the satisfaction they derive from their occupations and how they have progressed to their present positions. The questionnaires were sent out during July and August 1961, and completed questionnaires were received from 2,630 men and 494 women, or 70 per cent of all the men and 80 per cent of all the women graduates on the College lists for the appropriate years. The results are presented in six chapters covering, respectively, the graduates' background, their current employment, earnings and satisfaction of those working in the United Kingdom, the past and the future, men working overseas, and the women graduates.

Both men and women come of predominantly bourgeois background, only 2 per cent of the men being children of semi-skilled or unskilled workers. Nearly two-thirds of men, but a lesser proportion of the women, were educated at independent schools, but while most women went direct to Cambridge from school, only 17 per cent of the men did so, 66 per cent being otherwise occupied for one to three years, usually in National Service. Of the men, 31 per cent graduated in science or mathematics, 11 per cent in engineering, 9 per cent achieving first-class honours, 59 per cent second-class honours and 6 per cent an ordinary degree. Most of the men were in the age-group 29–33 and all but 434 were working in the United Kingdom, 349 of those being British nationals. At the time of the survey, 35 per cent of the women were working full time and 16 per cent part time, and out of 207 married women, 50 were working full time and 78 per cent part time, a very high proportion being teachers in schools and universities.

Of all men working in the United Kingdom, about 24 per cent were employed in teaching and 24 per cent in industry, of whom about a quarter were employed in research, design and development work, a similar proportion in sales and marketing, less than a fifth in production management and a slightly smaller proportion in general management. Of the teachers, three-fifths were schoolmasters, of whom only a quarter were teaching science, mathematics or engineering subjects, whereas in the universities and technical colleges, men teaching the latter subjects outnumbered those teaching arts subjects in the proportion 57 : 43. Medicine and commerce each claimed about 8 per cent of the whole group; 9 per cent were public servants in the Civil Service, local authorities or the Atomic Energy Authority (4 per cent in the Scientific Civil Service, 3 per cent in professional or specialist classes,

* *The Employment of Cambridge Graduates*. By Christine Craig. Pp. xi+102. (Cambridge: At the University Press, 1963.) 10*s*.

2 per cent in administration). Nearly 60 per cent of engineering graduates and 41 per cent of scientists and mathematicians were in industry, about 20 per cent of the latter being in universities and technical colleges and 16 per cent teaching in schools. About two-fifths of the arts men in industry were in commercial departments and a quarter in general management or the central services of industrial groups.

More than a third of all men with first-class honours were in university posts, about one in seven being in industry and professional practice. Only three schoolmasters in 100 had first-class honours and nearly 10 per cent had ordinary degrees. Most Ph.D.s were in universities or had research appointments elsewhere. Taking the total earnings, the middle members of the group of men working in the United Kingdom were receiving £1,500–£1,600; for basic earnings, the medium was £1,425, but for a quarter total earnings were less than £1,250; for another quarter they exceeded £2,000, and for 12 per cent £2,500. A third of the men in industry were earning more than £2,000, but nearly a quarter less than £1,500. Three-quarters of the schoolmasters fell in the group earning between £1,000 and £1,500 and only 3 per cent were earning more than £2,000, while only 7 per cent of university and technical college teachers earned more than £2,000. Teaching was the only occupation in which the men who considered their salary a fair return were outnumbered by those who thought otherwise, but even so, 50 per cent were satisfied. About a third of those employed in universities, in medicine and in private practice were dissatisfied, and about a quarter in industry. About 30 per cent of men in the universities expressed profound satisfaction. Men who entered paid employment within six months of graduation were mostly paid £400–£600 a year, and for four years after graduation the average salaries of men who had taken postgraduate courses were slightly lower than those of men who had entered employment immediately after graduation. While only 3 per cent of the men who went into the Church (6 per cent of the total) or the medical profession afterwards changed their profession, 58 per cent of the others changed their employers at least once between starting their first job and the time of the survey, 16 per cent making radical changes of occupation. About half the men expected to be with the same employer or in the same business in five years time.

Of the 434 men working overseas, 60 were in the United States, 58 in Canada and 131 in various African territories, and it is probable, but not certain, that at least half of those in Canada and a substantial proportion of those in the United States were permanently resident overseas. Of the 19 per cent in Government service, most were in Africa; 20 per cent were concerned with education in schools, 7 per cent were employed in universities, mostly in the United States, 20 per cent in industry and 13 per cent in commerce. Of the scientists and mathematicians, 16 per cent, and of the engineers 13 per cent, were overseas, 25 engineers or scientists being in the United States and 20 in Canada; of the 29 Ph.D.s overseas, 17 were in the United States, almost all in university posts. A third of the men overseas were earning the equivalent of £3,000 or more.

RIOMETER OBSERVATIONS OF IONOSPHERIC ABSORPTION DUE TO THE SOLAR FLARES OF APRIL 15, 1963

By S. HOROWITZ

Air Force Cambridge Research Laboratories, Bedford, Massachusetts

AND

S. C. GOLDMAN

Aerospace Research, Inc., Boston 35, Massachusetts

THE occurrence of a strong solar flare offers an excellent opportunity for determining the dependence of ionospheric absorption on the zenith angle of the incoming ionizing radiation. Early calculations for a simple Chapman layer[1] indicated a dependence of the absorption on the zenith angle θ of the form $(\cos\theta)^{3/2}$. Some recent experimental and theoretical results show that the 3/2 power is generally too high an exponent. Calculations by Nicolet[2] have shown that an important parameter in determining the dependence of absorption on zenith angle is the effective recombination coefficient α. The classical derivation assumes that both α and H, the scale height, are constant. However, this is not the case in any of the ionospheric regions. A recent work by Mitra and Jain[3] also considers the variability with altitude of α.

A riometer network, installed by the Air Force Cambridge Research Laboratories at various locations around the world, has yielded absorption data on the two Type II+ solar flares which occurred on April 15, 1963, beginning at 1123 U.T. and 1614 U.T., respectively. The first flare was accompanied by a severe noise storm which began about ten minutes after the conclusion of the first major period of absorption. All the riometers located on the sunlit side of the Earth observed these flares and absorption data obtained are given in this paper. The dependence of absorption on zenith angle is quite close to the value obtained by Appleton.

Riometer locations. Riometers which observed the solar flares of April 15 are listed in Table 1, along with the solar zenith angles at flare onset. All operating frequencies were 30 Mc/s with the exception of Bedford, Massachusetts, which also operated at 22 Mc/s, and Athens, Greece, where data was also obtained on 27·6 Mc/s and 58 Mc/s.

Table 1. SOLAR ZENITH ANGLES AT 1123 U.T., APRIL 15, 1963. COMPUTED FOR RIOMETER SITES

Site locations	Solar zenith angle
Accra, Ghana	10°
Addis Ababa, Ethiopia	29°
Athens, Greece	34°
Hermanus, Republic of South Africa	45°
New Delhi, India	63°
Bedford, Massachusetts	76°

Table 2 lists solar zenith angle information for the flare of 1614 U.T., April 15, 1953.

Table 2. SOLAR ZENITH ANGLE AT 1614 U.T., APRIL 15, 1963. COMPUTED FOR RIOMETER SITES

Site locations	Solar zenith angle
Bedford, Massachusetts	34°
Sacramento Peak, New Mexico	45°
Great Whale River, Quebec	47°
Accra, Ghana	62°
Athens, Greece	80°

Antennæ used were two-element, vertically directed Yagis operating over an artificial ground screen. Antenna beam-width was about 60° in the E-plane.

Absorption data. In some of the measurements, local interference was quite severe, and the accuracy of the measurements was somewhat degraded. However, at

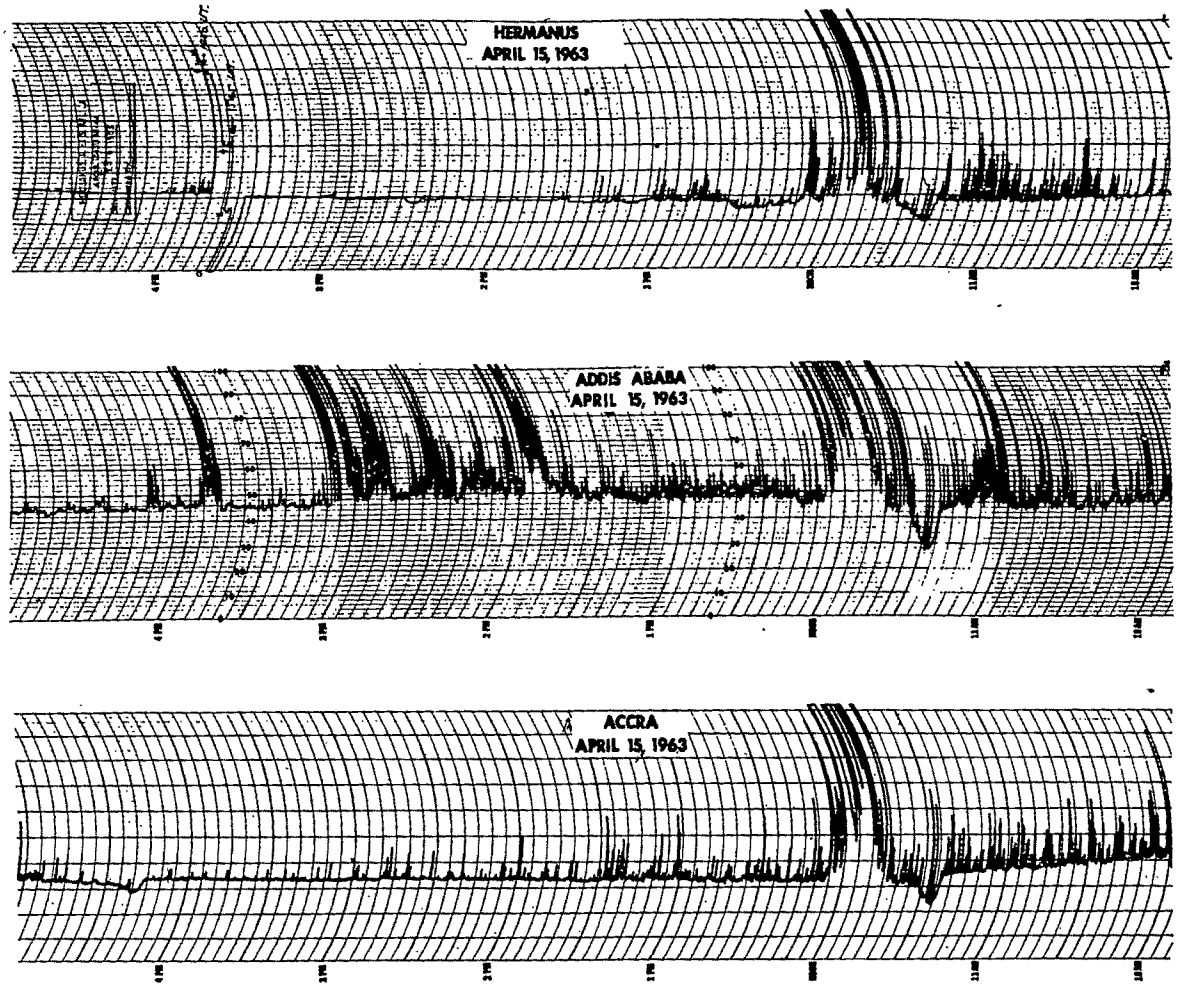

Fig. 1. Riometer effects on 30 Mc/s at African sites due to solar flare of April 15, 1963, at 1123 U.T.

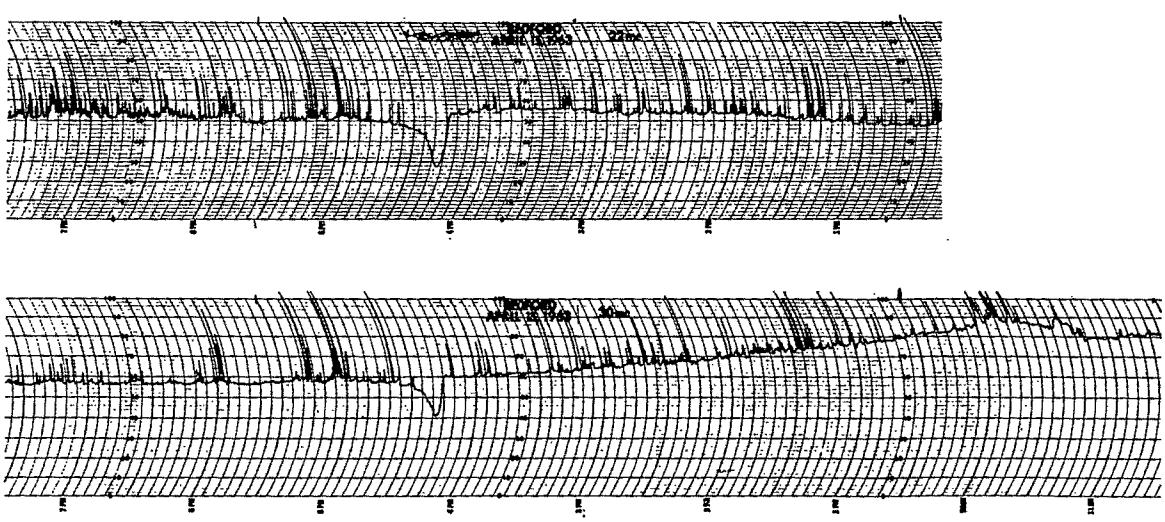

Fig. 2. Riometer effects on 22 Mc/s and 30 Mc/s at Bedford, Massachusetts, due to solar flare of April 15, 1963, at 1614 U.T.

those sites where relatively quiet conditions prevailed, measurements to $\pm 0{\cdot}1$ db are considered to be valid. In Fig. 1 is shown a photograph of the data obtained at three African sites. The occurrence of the first solar flare at 1123 U.T. is easily seen at all stations. The second solar flare is observed at Accra, which was the only station in sunlight at the time of the flare. 22 Mc/s and 30 Mc/s data obtained on the second flare at Bedford, Massachusetts, is shown in Fig. 2.

In Fig. 3 we have graphed the values of absorption due to the 1123 U.T. flare, as a function of solar zenith angle. On the same graph are plotted $\cos^n$ curves for $n = 1$ and $n = 3/2$. Within the limits of observational error, the 3/2 power curve is a better fit. The point at zenith angle of 10° (corresponding to Accra, Ghana) does not fall close to either curve. This anomaly may be due to the fact that the noise observed at Ghana was quite extreme and may have prevented the riometer signal from reaching

its minimum due to absorption. The data from the flare at 1614 U.T. is shown in Fig. 4 and once again, for comparison, the cosine function with the unity and three-halves exponents are shown. The quality of the data and the inaccuracy of the measurements at 80° zenith angle (due to a wide trace on the particular riometer) makes it somewhat more difficult to decide which curve the data is following. The 3/2 power curve appears to be a better fit, but this conclusion is not as clear as that reached from the earlier flare.

Frequency dependence. The operation of multi-frequency riometer installations at Athens, Greece and Bedford, Massachusetts, enables a study of the absorption dependence on frequency. For non-deviative propagation in the quasi-longitudinal mode, where $f \gg \nu$, the collision frequency, this absorption has often been shown to be dependent on the inverse square of the frequency. Fig. 5 shows this dependency and indicates that the absorption measured was occurring in the lower ionosphere.

Attenuation rate. Fig. 6 shows the elapsed time between onset of the flare and the time at which maximum absorption was recorded. These values show no clear dependence on zenith angle and indicate a time of about 3 min for the first flare and about 4 min for the second flare. The relation of the relaxation time of the absorption to the rate of recombination and electron attachment in the lower ionosphere is presently being studied.

Second absorption phase. Careful inspection of the data from Hermanus, Bedford, and Sacramento Peak, shows that a second absorption phase appeared. In the case of Hermanus, this second absorption reaches its maximum at about 1230 U.T. on the first flare. The second absorption phase at Bedford is somewhat complicated by the occurrence of local and solar noise; however, preliminary analysis indicates that the absorption maximum occurred at about 1740 U.T. Information relayed from Cape Hallet, Antarctica, indicates the occurrence of an absorption increase about one-half hour following each flare. Since this second absorption phase is not observed at the equatorial sites, it is possibly due to the arrival of solar charged particles[4].

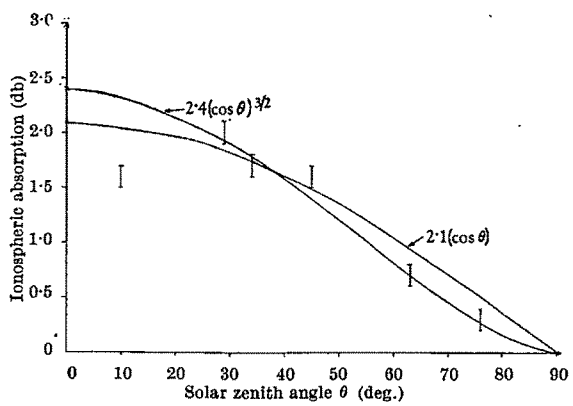

Fig. 3. 1123 U.T., April 15, 1963, solar flare absorption 30 Mc/s riometer

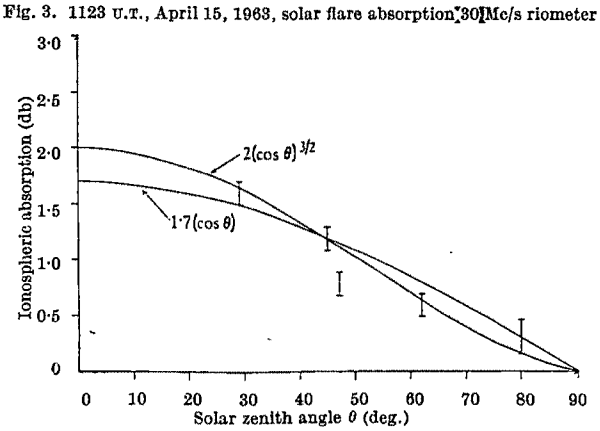

Fig. 4. 1614 U.T., April 15, 1963, solar flare absorption 30-Mc/s riometer

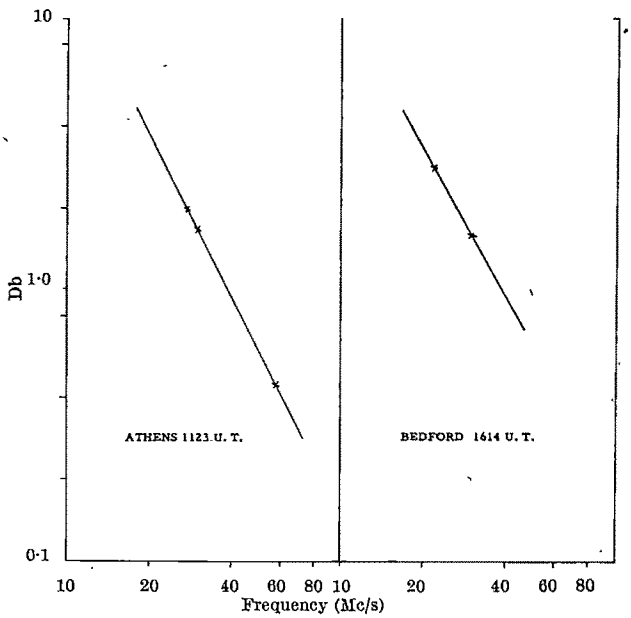

Fig. 5. Solar flares April 15, 1963, 1123 U.T. and 1614 U.T. Frequency dependence of absorption

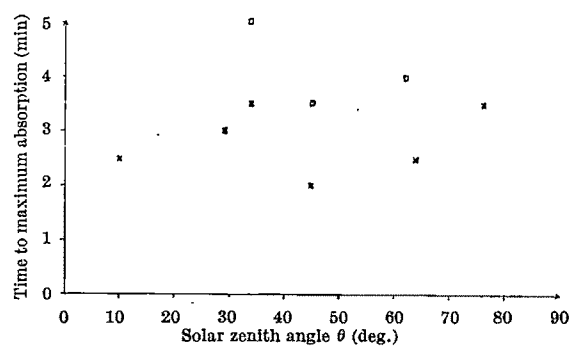

Fig. 6. 30 Mc/s riometer April 15, 1963. Time from flare onset to maximum absorption
×, Flare of 1123 U.T.; □, flare of 1414 U.T.

Conclusions. A network of riometers operating at 30 Mc/s has enabled a comprehensive study of the ionospheric absorption due to a solar flare. Riometers located at, or near, the geomagnetic equator have indicated effects which may be attributed solely to electromagnetic radiation. As one progresses farther from the equator it is possible to see the beginning of effects due to charged particles. A riometer located near the south geomagnetic pole indicated no electromagnetic effects and strong absorption effects due to incoming charged particles.

Since the electromagnetic and corpuscular effects can be separated, it is possible to determine the dependence on solar zenith angle of the flare-induced absorption at low and medium latitudes. This functional dependence is found to be close to the $\cos^{3/2}$ relationship derived from the simple Chapman layer. The dependence of this absorption on riometer frequency is found to be f^{-2}, which is the value expected for absorption in the quasi-longitudinal mode at medium latitude.

A NEW CALCULATION FOR THE AGE OF THE EARTH FROM ABUNDANCES OF LEAD ISOTOPES

By Dr. R. G. OSTIC
Department of Physics, University of British Columbia
AND
Prof. R. D. RUSSELL* and P. H. REYNOLDS*
Department of Physics, University of Toronto

THE only precise estimates that exist to-day for the age of the Earth are based on measurements of the isotopic composition of lead. Numerous calculations have been reported in the past[1], but only two[2,3] are of significance at the present time. In both, the assumption is implicit that the isotopic composition for the various lead samples can be related to an initial primeval lead by equations derived for a system which is closed with respect to uranium and lead. One calculation[2] assumes that the primeval lead isotope abundances are identical with those now observed in the troilite phase of iron meteorites, and evaluates the time required to change such lead into that found in one or more terrestrial samples of known age and isotopic composition. The second calculation[3] assumes that the leads now observed in stone meteorites represent the products of evolution from the primeval isotope ratios to their present values. Theory shows that such leads, in the absence of events fractionating lead and uranium during the lifetime of the meteorite, should have isotope ratios which lie on a straight line, and that the slope of this straight line can be used to determine the age of the meteorite system. Apart from the difficulty in proving the common assumption that equations for a closed system may be used in these calculations, the accuracy of the first calculation is limited by the uncertainty in assigning ages to the samples used, and of the second calculation by the uncertainty in equating the age of the Earth to the age of the meteorite system. The approximate equality of the values obtained by the two calculations provides some experimental justification for both procedures.

Recently considerable progress has been made in interpreting the isotopic composition of terrestrial lead samples[4]. The results suggest a third method for calculating the age of the Earth from lead isotope abundances which is basically distinct from the two mentioned above. In common with the others, the new method assumes that the samples used in the calculation can be interpreted by equations appropriate to evolution of the lead isotope abundances in a single closed system. It does not, however, require estimates to be made for any of the ages of the samples used, and it does not require the assumption that the age of the Earth is the same as the age of meteorites. It does assume that terrestrial leads have evolved in the Earth from lead similar in isotopic composition to that in the troilite phase of iron meteorites, and in fact the method provides an estimate for the time at which the Earth's lead had this isotopic composition. It also requires the assumption that the primary growth process for lead isotopes in the Earth occurred in a system or systems in which the uranium/lead ratio differed by a very small amount from the mean value, an assumption for which considerable evidence has been accumulating[5,6].

The calculation itself is very similar to one proposed several years ago by Allan, Farquhar and Russell[7]. If a closed system can be assumed for a particular lead sample, its age can be determined from both the $^{206}Pb/^{204}Pb$ and $^{207}Pb/^{204}Pb$ ratios according to the equations:

$$t = \frac{1}{\lambda}\log_e\left\{e^{\lambda t_0} - \frac{x - a_0}{\alpha V}\right\}$$
$$t' = \frac{1}{\lambda'}\log_e\left\{e^{\lambda' t_0} - \frac{y - b_0}{V}\right\} \qquad (1)$$

The symbols are defined in Table 1. In the right-hand side of equations (1) there are two unknown parameters, namely, V and t_0. (We have made the assumption that a unique value of V will describe the suite of samples closely enough.) It is formally possible to carry out a least-squares analysis of measured lead isotope ratios to determine values of both the foregoing parameters which give the most concordant t and t' values. Such a procedure is able to yield a reasonably precise value for t_0; we have followed two procedures and obtained two numerical estimates as detailed here.

Table 1. Definition of Symbols

Isotope ratio	Present ($t=0$)	Time t	Primeval ($t=t_0$)
$^{206}Pb/^{204}Pb$	a	x	a_0
$^{207}Pb/^{204}Pb$	b	y	b_0
$^{238}U/^{204}Pb$	αV	$\alpha V e^{\lambda t}$	$\alpha V e^{\lambda t_0}$
$^{235}U/^{204}Pb$	V	$V e^{\lambda' t}$	$V e^{\lambda' t_0}$

Physical constants: $\alpha = 137{\cdot}8$; $\lambda = 0{\cdot}1537 \times 10^{-9}$ yr.$^{-1}$; $\lambda' = 0{\cdot}9722 \times 10^{-9}$ yr.$^{-1}$.

First calculation. The first calculation requires that the mean, ordinary-lead growth-curve originates at the primeval abundances $(a_0, b_0) = (9{\cdot}56, 10{\cdot}42)$ given by Murthy and Patterson[8]. In order to select suitable samples which are unlikely to be anomalous we have used analyses for galenas from deposits selected by Stanton[9] as being representative of his 'conformable' or 'pyritic conformable' classification. Previous work[4,5] has indicated that this geological criterion, although not perfect, more successfully excludes anomalous leads than any other known.

Table 2. Summary of Results

Location	x	y	z	t_{app} (Gyr.)	$(^{238}U/^{204}Pb)_{app}$	Residual	t_0 (Gyr.)
1. Primeval Abundances, Murthy and Patterson, (1962)	9·56	10·42	29·71	4·53	9·21	475	4·53
2. Manitouwadge, Ontario (Mean of 3 samples)	13·403	14·565	33·545	3·03	9·62	600	4·48
3. Broken Hill, Australia (Mean of 6 samples)	16·117	15·539	36·087	1·61	8·92	575	4·56
4. Mount Isa, Australia (Mean of 5 samples)	16·210	15·593	36·219	1·46	8·50	1,530	4·61
5. Sullivan Mine, B.C. (Mean of 2 samples)	16·633	15·638	36·577	1·28	8·79	1,000	4·58
6. Captain's Flat, Australia (Mean of 7 samples)	18·178	15·766	38·564	0·47	9·26	508	4·52
7. Cobar, Australia (Mean of 10 samples)	18·205	15·771	38·543	0·46	9·29	543	4·52
8. Bathurst, New Brunswick (Mean of 3 samples)	18·291	15·781	38·526	0·42$_5$	9·34	606	4·52
9. Hall's Peak, Australia (Mean of 6 samples)	18·490	15·754	38·770	0·15	9·04	492	4·54
10. White Island, New Zealand (Mean of 2 analyses)	18·885	15·750	39·070	−0·25	8·85	640	4·56
Mean ± standard deviation of the mean					9·08 ± 0·11		4·54 ± 0·02

* Present address: Department of Geophysics, University of British Columbia.

We have used only isotopic analyses carried out at the University of British Columbia, since we believe these to be the most precise galena analyses available. The analyses are shown in Table 2. Samples from Rosebery, Tasmania (18·374, 15·746, 38·469), which should be included on the basis of the foregoing criteria, have been excluded from the calculation. They are known to be part of an anomalous lead suite which includes vein leads from Mount Farrell. Some of the other samples may be slightly anomalous, too. Fortunately, the calculation is extremely insensitive to this provided that the anomalous component is not more than about 10 per cent of the total lead. For example, the inclusion of Rosebery would increase t_0 by less than 0·25 per cent, and the rejection of any sample used in the calculation (except for a_0 and b_0) would alter the result by a similar small amount.

We have interpreted best concordance between t and t' as corresponding to the minimum value of the expression:

$$\text{residual} = \sum_{i=1}^{n} W_i(t_i - t'_i)^2 \qquad (2)$$

The weight function, W_i, is included after Bullard and Stanley[1] to ensure that the result obtained is independent of the exact nature of the definition of the residual and is the most probable value. It is defined by the relationships:

$$1/W_i = \left(\frac{\partial \Delta t_i}{\partial x}\right)^2 \delta x^2 + \left(\frac{\partial \Delta t_i}{\partial y}\right)^2 \delta y^2$$

and:

$$\Delta t_i = t_i - t_i'$$

where δx and δy are the estimated experimental uncertainties in the measured ratios. The present calculation assumes $\delta x = \delta y$; the numerical value is immaterial.

The expression for Δt_i is non-linear in both V and t_0, and we have expanded it as a Taylor series in δV, the deviation from an approximate value **V**. Then condition (2) becomes*:

$$\text{residual} = \sum_{i=1}^{n} \mathbf{W}_i \left(\Delta t_i + \frac{\partial \Delta t_i}{\partial V}\,\delta V + \ldots\right)^2 = \text{minimum}$$

* Bold-faced symbols indicate that the quantity has been evaluated with **V**. By $\frac{\partial \Delta t_i}{\partial V}$ we mean the value of the derivative obtained with **V**.

The best value of V corresponding to a given t_0 is obtained by applying repeatedly corrections given by:

$$\delta V = -\frac{\sum_{i=1}^{n} \left\{\mathbf{W}_i \cdot \Delta t_i \cdot \frac{\partial \Delta t_i}{\partial V}\right\}}{\sum_{i=1}^{n} \left\{\mathbf{W}_i \cdot \left(\frac{\partial \Delta t_i}{\partial V}\right)^2\right\}}$$

until the procedure converges to the best V value. In all cases we have tried, the process converges to a unique result, although as many as sixteen iterations may be required.

The least-squares solution for V was obtained for each of t_0 = 4·49, 4·52, 4·55, 4·58, 4·61, and the minimum residual evaluated for each. These are plotted on an arbitrary scale in Fig. 1. The well-defined minimum at 4·53 Gyr. is the best value for t_0 in a least-squares sense. The corresponding value for αV is 9·21 atoms/atom. The sharpness of the minimum is a measure of the precision of the estimate of t_0. A good approximation to the standard deviation of t_0 is obtained by dividing the half-width at double minimum residual by the square root of two less than the number of samples. The standard deviation so evaluated is 0·03 Gyr. (obtained by rounding up 0·025).

For the purpose of comparison, we have carried out a similar, though simpler analysis of meteoritic data, with results shown in Fig. 2. In this case the stone meteorites were assumed to be of zero age, and would therefore lie on the isochron of zero age, given by the equation:

$$\frac{y - b_0}{x - a_0} = \frac{e^{\lambda' t_0} - 1}{\alpha(e^{\lambda t_0} - 1)}$$

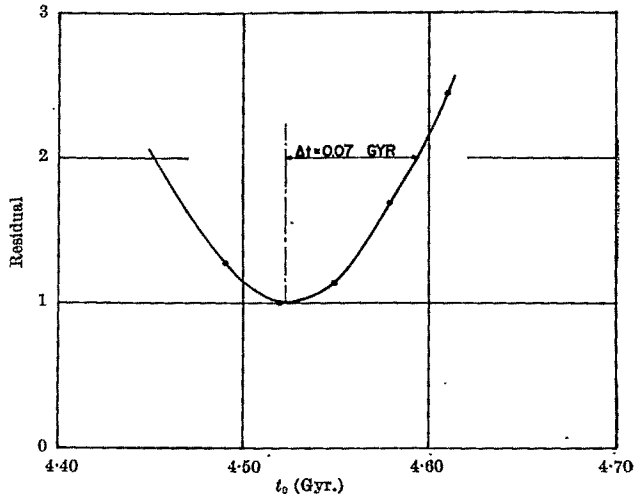

Fig. 1

The residual, equal to the sum of the perpendicular distances between the observed meteoritic ratios and the isochron of zero age, was calculated for different values of t_0. The two curves show the result of using analyses for only three stone meteorites by Patterson, and forty-eight of various types from several laboratories. The ages and standard deviations obtained from the figure are 4·56 ± 0·03 Gyr. and 4·56 ± 0·02 Gyr. This compares well with Murthy and Patterson[7], who give a slope of 0·59 ± 0·01 for the zero isochron, which corresponds to t_0 equal to 4·55 ± 0·03 Gyr.

Second calculation. A criticism of the first calculation is that it assumes an exact knowledge of the primeval lead abundances. Substituting the older Patterson values (9·50, 10·36) changes the result by a negligible amount, but the 1·5 per cent uncertainty of the ratios estimated by Murthy and Patterson could result in an error of forty million years in t_0.

The following procedure avoids placing excessive weight on the primeval abundances. In equations (1), with the assumption that an average V provides a reasonable representation of the samples, a_0, b_0 and t_0 need not be interpreted as primeval values, but can correspond to any point through which the growth-curve is forced to pass. Then it is formally possible to force the curve through any of the samples in Table 2, and calculate the apparent age of the sample and the apparent V-value. From these two numbers it is possible to use either of

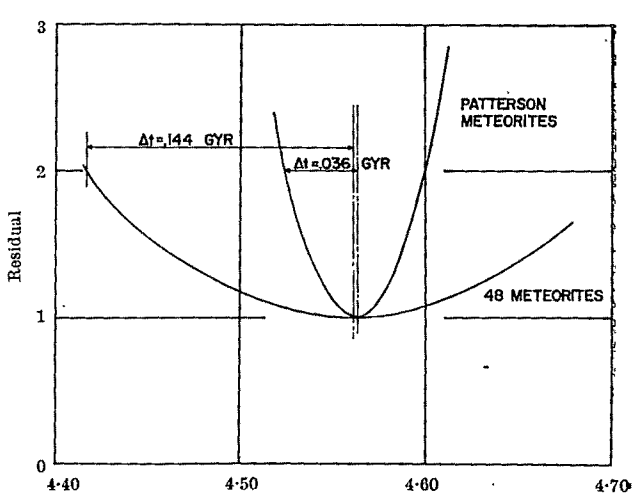

Fig. 2

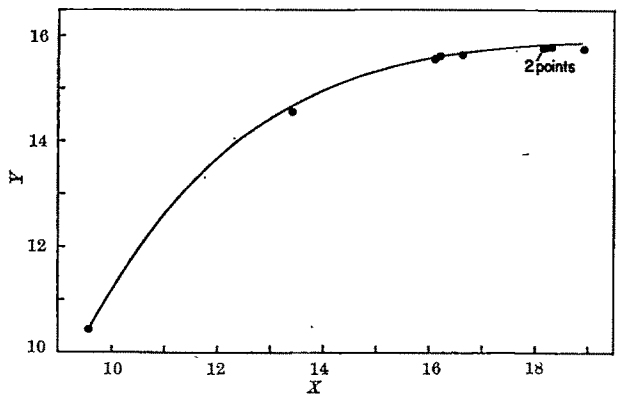

Fig. 3

equations (1) to calculate the time t_0 at which terrestrial-lead had the primeval ratios. Using the mathematical procedures described here, the growth-curve was forced through each point in turn, the two values of t_0 were calculated in each case and the results were averaged to give the ages shown in Table 2. The greatest difference between the two times, which was obtained when the curve was forced through the Mount Isa abundances, amounted to less than 0·3 per cent. This agreement supports the basic assumption of a unique growth curve. By averaging the t_0 values obtained, we arrive at a result which does not weight the primeval abundances so heavily. The result obtained is 4·54 ± 0·02 Gyr., where the uncertainty quoted is the standard deviation of the mean (rounded up from 0·014).

Conclusion. Either of the results obtained, 4·53 ± 0·03 Gyr. or 4·54 ± 0·02 Gyr., provides an estimate of the time at which terrestrial lead had the same isotopic composition as the troilite phase of iron meteorites. The procedure avoids both the necessity of assigning ages to terrestrial samples and the assumption that the age of the Earth is equivalent to the age of meteorites. Thus the agreement of the present result with the age of meteorites obtained from the slope of the meteoritic isochron (4·55 ± 0·03 Gyr.) provides valid independent evidence that the two events occurred at about the same time.

The essential assumption of the calculation, that the samples used can be represented by a single growth curve, is justified by Fig. 3, which shows the experimental points plotted on such a growth-curve calculated for $t_0 = 4{\cdot}53$ Gyr. and $V = 0{\cdot}0670$ ($aV = 9{\cdot}21$).

ADSORPTION OF KRYPTON AND XENON ON EVAPORATED METAL FILMS IN RELATION TO THE DETERMINATION OF SURFACE AREA AND THE NATURE OF ADSORBED CARBON MONOXIDE

By D. BRENNAN, M. J. GRAHAM, and F. H. HAYES

Department of Inorganic, Physical and Industrial Chemistry, University of Liverpool

THERE is a growing tendency to use the adsorption of xenon for surface area measurements, especially for small areas, because the low value of P_0(Xe) enables useful values of P/P_0 to be reached with conventional apparatus without incurring the penalty of large dead volume corrections. However, there is some uncertainty concerning the effective cross-sectional area (σ) of xenon which should be used for this purpose. Thus, Singleton and Halsey[1], using nitrogen as the reference adsorbate with $\sigma(N_2) = 16{\cdot}2$ A^2, obtain values of σ(Xe) as follows: 20·2 A^2 on carbon black, 18·2 A^2 on silver iodide and 27·3 A^2 on anatase; the Brunauer–Emmett–Teller method was used, except for carbon black for which it was unsatisfactory and the point B was used instead. Later work would seem to favour a value σ(Xe) = about 24 A^2. Van Heerden and Zwietering[2], using carbonyl iron as the adsorbent, obtained σ(Xe) = 22·3 A^2 from a comparison between the adsorption of xenon, krypton and ethylene; no details of this study are provided. Pritchard[3] gives σ(Xe) = 24 A^2; this value was obtained by comparison of the monolayer volume, estimated by following the change in surface potential when xenon was adsorbed on copper, with the krypton Brunauer–Emmett–Teller area, using σ(Kr) = 19·5 A^2. Support for this value has been given recently by Cannon[4] who reports σ(Xe) = 25 A^2 as the result of comparison of Brunauer–Emmett–Teller monolayer volumes for xenon and krypton, again with σ(Kr) = 19·5 A^2, nickel powder and oxidized nickel powder being the adsorbents. However, the need for caution in assigning a value to σ(Xe) is indicated by the work of Ponec and Knor[5], who adsorbed xenon and krypton on evaporated films of nickel, and obtained σ(Xe) = 13·8 or 17·2 A^2, depending on the method of assessment of the monolayer volume, with σ(Kr) = 19·5 A^2 as the reference value; theirs is the only published result in which the effective area of xenon is smaller than that of krypton. Again, Anderson and Baker[6] have attempted to estimate σ(Xe) using evaporated films of nickel and tungsten, and they emphasize the importance of lattice parameters in determining the availability of sites for adsorption. They interpret the variety of σ(Xe) values reported by Singleton and Halsey[1] in these terms and quote average effective values σ(Xe) = 23·0 and 19·5 A^2 for polycrystalline tungsten and nickel films respectively, and σ(Kr) = 17·9 A^2 for nickel films.

This article describes an investigation into the value of the ratio σ(Xe)/σ(Kr) determined for evaporated films of titanium, zirconium, iron, cobalt, nickel, molybdenum, tungsten, tantalum and platinum at 77° K. The procedure followed in every case was to obtain successively the adsorption isotherm for xenon, krypton and then xenon again, on the same film with complete removal of adsorbate prior to each determination. The requirement that the first and the last xenon isotherms be superimposable, or very nearly so, leaves no doubt that all the isotherms refer to precisely the same surface. The films were

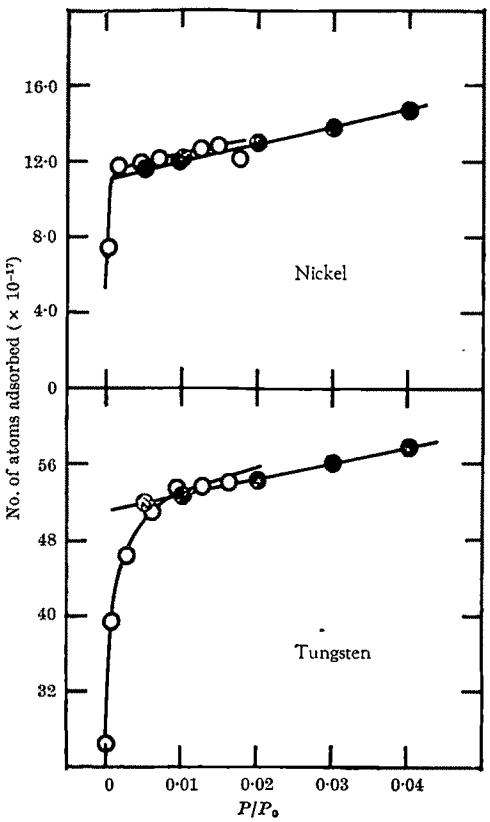

Fig. 1. The 77° K isotherms for the adsorption of krypton (○) and xenon (●) on evaporated films of nickel and tungsten

deposited in a vacuum of the order of 10^{-8} torr using a conventional adsorption apparatus adapted for bakeout by inclusion of water-cooled greased stopcocks[7]. The krypton used was supplied by British Oxygen Co., Ltd., in break-seal ampoules, the purity being 99–100 per cent, with xenon as the possible impurity. The xenon used was similarly supplied, but was found to contain a more volatile impurity which was removed by repeated distillation into a trap at 77° K with pumping. The value of $P_0(\mathrm{Xe}) = 2{\cdot}3 \times 10^{-3}$ torr at the temperature of a liquid nitrogen cold trap was obtained on several occasions and with different samples of the gas. Corrections for thermal transpiration were made by means of the equation of Bennett and Tompkins[8], which was found by Podgurski and Davis[9] to be very satisfactory for xenon. Our value for $P_0(\mathrm{Xe})$ is not seriously different from $P_0(\mathrm{Xe}) = 1{\cdot}7 \times 10^{-3}$ torr at 77° K derived from the very careful measurements of Podgurski and Davis and such discrepancy as there is corresponds to an uncertainty of only one degree in bath temperature. For the purpose of Brunauer–Emmett–Teller calculations, $P_0(\mathrm{Kr}) = 3$ torr was used; at the very low values of P/P_0 involved, the method is not sensitive to P_0 and the equation is virtually the Langmuir isotherm. The results are summarized in Table 1 and two typical isotherms are shown in Fig. 1. The Brunauer–Emmett–Teller equation provides a useful

Table 1. Comparison of Monolayer Values obtained for Krypton and Xenon on the same Evaporated Film by the Brunauer–Emmett–Teller (B.E.T.) and Point *B* Methods

Metal	Weight of film (mg)	Monolayer coverages (atoms × 10^{-17}) Point *B* Kr	Point *B* Xe	B.E.T. Kr	B.E.T. Xe
Co	64·8	12·4	13·9	14·1	16·2
Ni	65·3	11·6	11·0	12·5	13·2

Ti	15·8	—	20·8	23·2	22·3
Zr	35·3	—	16·9	21·2	19·8

criterion of monolayer coverage only when applied to the isotherm in the region of point *B*. Because the heats of adsorption for these systems are relatively great, the point *B* occurs at relative pressures of 0·01 or less. If Brunauer–Emmett–Teller plots are used for relative pressures much greater than this, unreliable estimates of the monolayer values are likely to be obtained, even though the plots may be reasonably straight; this criticism may be made of the data of Cannon[4]. Again, when very small areas are used, great care must be made in applying various corrections and difficulties may arise owing to this cause also[4].

Examination of Table 1 reveals a notable similarity in the numbers of krypton and xenon atoms adsorbed by the same film for a given criterion of monolayer coverage. Only in the case of iron is the number of krypton atoms in a monolayer significantly greater than of xenon. We conclude, consequently, that, in general, the effective areas of krypton and xenon atoms on these metals are virtually the same.

If it were not for the long tradition of assigning unique areas to physically adsorbed molecules, and some recent experimental work, this result would perhaps not be too surprising. The field emission microscope has amply demonstrated the importance of co-ordination number of a substrate site in the adsorption of the inert gases[10,11], and the relatively large energy of activation for surface diffusion observed for krypton and xenon on tungsten[11,12] is further evidence that these adatoms are located on surface sites. We have tried to assess the interatomic energy for all the various conceivable configurations of krypton and xenon atoms on these metals, using 6–9 and 6–12 Lennard–Jones type potential energy functions and the exp–6 function as limiting cases[13,14], with the object of excluding those configurations that seem to involve a prohibitively large repulsive energy. The conclusions reached from this analysis, which will be presented in detail elsewhere, are that apart from zirconium, which has the largest lattice spacings, there is no likelihood of adsorbing more krypton atoms than xenon atoms on these metals, and, even for zirconium, the possibility of doing so is not strong.

Additional support for the view that these atoms are held on surface sites can be found in the values of the ratio:

$$p = \frac{\text{No. of carbon monoxide molecules adsorbed}}{\text{No. of krypton atoms adsorbed by the clean surface}}$$

Since the clearest deductions can be made for titanium and zirconium, for which p (experiment) = 1·78 and 1·05 respectively, the discussion will here be confined to these two metals. It would not be expected, *a priori*, that titanium and zirconium would behave dissimilarly towards carbon monoxide and it is the present contention that, in fact, they do not. Their difference lies in the ability of zirconium to adsorb more krypton per given number of surface atoms than can titanium. The greater lattice spacings of zirconium make available sites which may be occupied by krypton atoms without excessive interatomic repulsion, while occupation of the corresponding sites on the surface of titanium would involve prohibitive overlap by neighbouring atoms. The argument can be extended to show that carbon monoxide is held on these two metals by bridge bonds, each surface metal atom being bounded to only one carbon atom. Repulsive interaction between neighbouring molecules is insufficient to prevent each surface metal atom carrying one carbon monoxide molecule, if bonding were linear carbon monoxide, or being bounded to two carbon atoms, if there were orbitals available for this purpose. The observed values of p are much smaller than the values expected for these two possibilities, but in good agreement with the requirement that each surface atom has available only one orbital for bonding with carbon monoxide in a bridge

configuration. These conclusions are unequivocal for titanium and zirconium; for the other metals the distinctions are not clear and argument by analogy is necessary.

One of us (F. H. H.) is in receipt of a maintenance grant from the Department of Scientific and Industrial Research.

PARTIAL REVERSIBILITY OF THE $Ca^{\cdot\cdot}$ – ITP-CONTRACTION OF GLYCEROL-EXTRACTED MUSCLE

By Prof. W. KUHN, I. TOTH and A. RAMEL
Physical Chemistry Institute, University of Basle

It is known that chemical energy can be transformed directly into mechanical energy by means of macromolecular filaments dilating and contracting under the influence of chemical changes. This energy transformation was found in all cases to be associated with the phenomenon that mechanical stretching produces a chemical equilibrium shift leading to an increase in the embedding medium of the reactants producing the contraction and a decrease in the activity of the reactants producing the dilation of the filaments (teinochemical principle)[1-3].

If $n_{1,\mathrm{tot}}$ is the number of moles of a given teinochemically active substance present in the total system (consisting of the gel filament and the embedding liquid), a_1, the activity of the substance in the embedding liquid, L, the length of the filament, and $\mathfrak{K}$, the mechanical force acting on it, the expression characteristic for a reversible and quantitative energy transformation reads:

$$-\left(\frac{\partial n_{1,\mathrm{tot}}}{\partial L}\right)_{\mathfrak{K}=\mathrm{const}} = \left(\frac{\partial \mathfrak{K}}{\partial L}\right)_{n_{1,\mathrm{tot}}=\mathrm{const}} \cdot \frac{1}{RT\left(\frac{\partial \ln a_1}{\partial L}\right)_{n_{1,\mathrm{tot}}=\mathrm{const}}} \qquad (1)$$

Equations similar to equation (1) hold independently for each teinochemically active substance present in the system[4]. The validity of equation (1) has been tested with a number of artificial filaments and afterwards also with filaments prepared from a natural muscle (suitably prepared earthworm muscular system)[5].

Corresponding experiments will here be described for the $Ca^{\cdot\cdot}$–ITP-contraction of the glycerol-extracted rabbit psoas muscle. We confirm the statements published by several authors that the glycerinated psoas contracts with ATP (or ITP) under certain conditions only if a minimum concentration of $Ca^{\cdot\cdot}$-ions is present in the system[7-9]. In our experiments the teinochemical behaviour of $Ca^{\cdot\cdot}$ in this system was tested with the use of equation (1).

Fibre bundles of glycerol-extracted rabbit psoas muscle, prepared according to the procedure described by Szent-Györgyi[6], were first soaked in de-ionized water to remove glycerol and afterwards in magnesium chloride solutions to extract exchangeable calcium.

All materials used were of analytical grade, purchased from E. Merck AG, Darmstadt.

ITP (trisodium salt, purum) was obtained from Fluka AG, Switzerland. Cations were removed before use with 'Dowex 50X8'. Concentrations were adjusted spectrophotometrically and the *p*H by neutralization with magnesium hydroxide.

Concentrations of calcium were determined spectrophotometrically with a Unicam 900 flame spectrophotometer.

Inorganic phosphate with a Unicam ultra-violet spectrophotometer 700, according to a modified procedure of Fiske–Subbarow, Unicam method sheet No. 500/6.

The length of the fibre bundles was measured cathetometrically.

For apparative details concerning the mechanical stretching of the bundles see ref. 3.

A psoas muscle sample of about 0·05 g, having a length (L) of 2·24 cm, was suspended at 5° C in 10 ml. of 0·01 M magnesium chloride. After 8 h the solution was replaced by a fresh one of equal composition, and extraction was continued under equal conditions for a further 8 h. About 0·2 μmole of $Ca^{\cdot\cdot}$ could be removed in the first step, and further 0·02 μmole approximately in the second.

The fibre bundle was then transferred into a cylindrical cell containing 2·5 ml. 0·01 M ITP, 0·01 M magnesium chloride, *p*H 7·4.

The unloaded fibre bundle contracted under these conditions from 2·2 cm to a length of 2·0 cm. This contraction is most likely caused by traces of $Ca^{\cdot\cdot}$ still present in the bundle.

Addition of calcium chloride in quantities of $3{\cdot}5 \times 10^{-8}$ to 7×10^{-8} moles in each step to the embedding solution produced an additional contraction, represented in Fig. 1. From the quantities indicated in the figure we obtain for the left-hand side of equation (1):

$$\left(\frac{\partial n_{1,\mathrm{tot}}}{\partial L}\right)_{\mathfrak{K}=0} = 1{\cdot}1 \times 10^{-6} \text{ mole cm}^{-1} \qquad (2)$$

The $Ca^{\cdot\cdot}$ concentration in the embedding liquid was at this stage of the experiment $4{\cdot}3 \times 10^{-5}$ mole/l., and the length of the unloaded muscle was 1·88 cm. The concentration of inorganic phosphate in the embedding medium increased by about 2×10^{-4} mole/l., indicating a corresponding decomposition of the ITP contained in the system.

The muscle was then stretched mechanically by a force $\Delta\mathfrak{K} = 1{,}800$ dynes, producing an increase in length of $\Delta L = 0{\cdot}24$ cm, corresponding to a value:

$$\left(\frac{\partial \mathfrak{K}}{\partial L}\right)_{n_{1,\mathrm{tot}}=\mathrm{const}} = 7{\cdot}5 \times 10^{3} \text{ dynes·cm}^{-1} \qquad (3a)$$

After establishment of the new equilibrium the $Ca^{\cdot\cdot}$ concentration was found to be $4{\cdot}7 \times 10^{-5}$ mole/l. The relative increase of the $Ca^{\cdot\cdot}$-concentration in the embedding liquid, associated with the mechanical stretching (3*a*), was thus:

$$\frac{1}{a_1}\frac{\partial a_1}{\partial L} = \left(\frac{\partial \ln a_1}{\partial L}\right)_{n_{1,\mathrm{tot}}=\mathrm{const}} = 0{\cdot}37 \text{ cm}^{-1} \qquad (3b)$$

With the numerical values (3*a*) and (3*b*) and with $RT = 2{\cdot}4 \times 10^{10}$ ergs/mole we obtain for the right-hand side of equation (1):

$$\left(\frac{\partial \mathfrak{R}}{\partial L}\right)_{n_{1,tot}} \Big/ RT\left(\frac{\partial \ln a_1}{\partial L}\right)_{n_{1,tot}} = 0{\cdot}85 \times 10^{-6}\ \text{mole.cm}^{-1} \quad (3c)$$

in rather good agreement with equation (2).

The mechanical force which had produced the stretching and the liberation of $Ca^{\cdot\cdot}$ from the muscle was finally reduced to zero; the muscle contracted correspondingly whereby the $Ca^{\cdot\cdot}$-concentration in the embedding medium decreased from $4{\cdot}7 \times 10^{-5}$ to $4{\cdot}44 \times 10^{-5}$ mole/l. It is noticed that the uptake of $Ca^{\cdot\cdot}$ when reducing the load is only about 70 per cent of the release of $Ca^{\cdot\cdot}$ when increasing the load. Analogous results were obtained with other muscle samples.

The values for $\left(\frac{\partial n_{1,tot}}{\partial L}\right)_{\mathfrak{R}}$ and for $\left(\frac{\partial \ln a_1}{\partial L}\right)_{n_{1,tot}}$ depend considerably on the actual calcium content of the muscle and also on the ITP concentration of the embedding liquid. Under favourable conditions (low calcium content of the muscle), a $Ca^{\cdot\cdot}$ concentration increase in the embedding liquid as high as by a factor of 3 could be observed to be associated with a 20 per cent mechanical stretching of the muscle. Stretching in presence of ITP and $Mg^{\cdot\cdot}$ can be applied as an alternative means instead of washing with magnesium chloride solutions to withdraw $Ca^{\cdot\cdot}$ from the muscle.

The $Ca^{\cdot\cdot}$ uptake and the $Ca^{\cdot\cdot}$ release associated with the contraction and the mechanical dilation of the glycerol-extracted psoas muscle proves that $Ca^{\cdot\cdot}$ under the conditions of our experiment is a teinochemically active substance which is bound chemically in the fibre when it contracts. Hence, $Ca^{\cdot\cdot}$ is not only a catalyst for other processes involved in the contraction.

If the process of contraction under these conditions includes formation of chemical bonds—fixing $Ca^{\cdot\cdot}$ inside the fibre—the free energy corresponding to the formation of these bonds undoubtedly becomes a part of the total chemical free energy which is displayed and the equivalent of which appears as mechanical energy produced in the contraction. The free energy corresponding to the reaction ITP → IDP + inorganic phosphate (which also occurs) will therefore only be a part of the total chemical free energy associated with the contraction. Equality of the mechanical energy produced in one contraction and the free energy of ITP (or ATP) splitting, which has been suggested by several authors, is therefore not to be expected. It can only be true approximatively, that is, if the free energy of the $Ca^{\cdot\cdot}$ binding is neglected.

Within the rough approximation in which the validity of equation (1) has been ascertained, the glycerol-extracted muscle in the presence of ITP must be considered to be a system able to transform into mechanical energy reversibly and quantitatively the free energy of dilution of $Ca^{\cdot\cdot}$ solutions or the free energy of chemical reactions by which $Ca^{\cdot\cdot}$-ions are produced or eliminated from the solution.

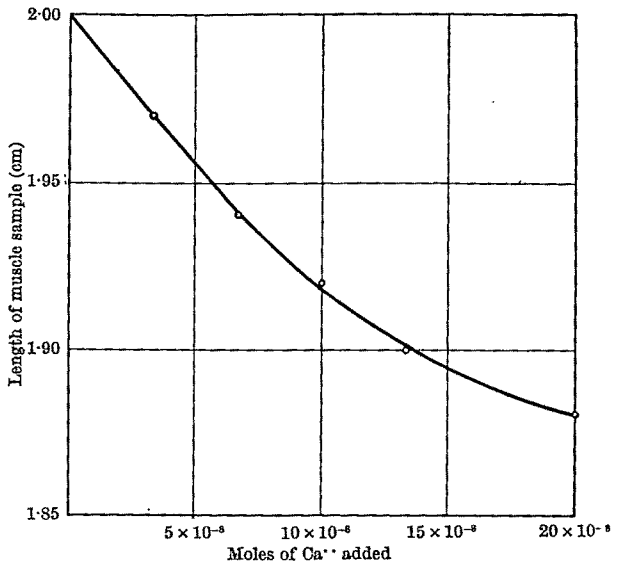

Fig. 1. Change of length of an unloaded washed muscle sample in 2·5 ml. of embedding liquid containing 10^{-3} moles of ITP and 10^{-2} moles of $Mg^{\cdot\cdot}$ per litre on addition of calcium chloride (abscissa)

We have stated that the reversibility observed is only partial in that the $Ca^{\cdot\cdot}$ release and uptake was only about 70 per cent reversible; it is partial, furthermore, in that the reversibility of the ITP splitting, which is also associated with the contraction, has not been ascertained yet. It is possible that the incomplete reversibility hitherto observed results from the presence in the system of enzymes catalysing irreversible reactions superimposed to the 'ideally' reversible $Ca^{\cdot\cdot}$–ITP-contraction.

The 70 per cent reversibility of $Ca^{\cdot\cdot}$ uptake and release associated with a mechanical change in length of the glycerol-extracted psoas muscle, satisfying approximately the teinochemical equation (1), indicates that the teinochemical laws established in the case of artificial macromolecular systems are also valid in principle for the glycerol-extracted muscle and we believe that this represents a first demonstration of an at least partial teinochemical reversibility of the elementary process of muscle contraction.

EFFECTS OF AIR, OXYGEN AND 20 PER CENT CARBON DIOXIDE ON THE RABBIT DURING SURFACE COOLING DOWN TO CARDIAC ARREST

By Dr. BRYAN BROOM*

Institute of Clinical Research, Middlesex Hospital Medical School, London, W.1

I HAVE shown[1] that in the rat the inhalation of 20 per cent carbon dioxide in oxygen, as opposed to 25 per cent air in oxygen, significantly increases the cooling rate while the animal is in a deep freeze at 0° C; an effect dependent on the prior removal of the fur.

The work recorded here has been undertaken to ascertain whether 20 per cent carbon dioxide accelerates cooling in the rabbit and, if so, whether this acceleration is affected by pentobarbitone anæsthesia; the effects of both 20 per cent carbon dioxide and hypothermia on the electroencephalograph, the electrocardiograph and the arterial pressure have also been assessed.

* Beit Memorial Research Fellow, Department of Physiology.

Table 1

	Air with pentobarbitone	20% CO_2 in air	20% CO_2 in air with pentobarbitone	Oxygen with pentobarbitone	20% CO_2 in oxygen	20% CO_2 in oxygen with pentobarbitone	Oxygen	Air
Time to unconsciousness (min)	155	180	105	160	225	115	1,000	1,100
Temperature when unconscious (° C)	19·6	21·8	21·8	19·2	21·4	22·2	16·0	17·0
Time to cardiac arrest (min)	220	260	175	220	315	195		
Temperature of cardiac arrest (° C)	12·0	11·8	8·4	10·0	7·2	7·0		

Body fur (40 g ± 10 g) was removed with scissors under pentobarbitone anæsthesia more than 48 h before each experiment. Forty-eight male rabbits of various strains (mean weight 2·8 kg ± 400 g) were used. The rabbit was placed in a cylindrical tin 25 × 15 cm (obtained from the Pharmacy Department) to one end of which was fitted a 'Perspex' chamber 12·5 cm × 12·5 cm × 12·5 cm, to which was attached a brass tube to receive gas tubing from the gas cylinders. The other end of the tin comprised a detachable lid, protected on the inside by a baffle, from which the effluent gases passed through another brass tube.

The rabbits were then subjected to chilling in the aforementioned tin at −20° C (± 4° C) with various inspiratory gas mixtures—air, oxygen, or 20 per cent carbon dioxide in either gas—with or without pentobarbitone anæsthesia, according to prior random selection. The inspiratory gas flow rate was 2 l./min. Pentobarbitone anæsthesia, when appropriate, was effected by an intravenous solution of pentobarbitone 50 mg/kg (± 15 mg/kg).

On reaching a temperature of about 20° C rectal the rabbit is deeply unconscious, and tracheotomy is quickly performed without mechanical restraint, ventilation afterwards being maintained by manual operation of an anæsthetic bag until cardiac arrest.

After tracheotomy the rabbit was placed on the floor of the deep freeze until cardiac arrest; electroencephalographic, electrocardiographic and temperature recordings being started in those rabbits initially unanæsthetized, and being continued in those already under pentobarbitone anæsthesia. The initially unanæsthetized rabbits breathing pure air and those breathing pure oxygen were left in the tin until unconsciousness supervened, their duration in the tin and final rectal temperature being noted. The interval between unconsciousness and death was rapid (about 10 min) in those animals given neither 20 per cent carbon dioxide nor pentobarbitone, though time was sufficient for some electrocardiographs to be recorded and these were all found to be grossly disrupted. Two rabbits in each of these groups showed no change in rectal temperature or conscious level after more than 20 h.

For the recording of arterial pressure, four unclipped anæsthetized rabbits were used; the rabbit was placed directly on the floor of the deep freeze at 0° C and the actual height of the column of blood in a polythene tube, inserted into the abdominal aorta through the femoral artery, was measured. The tube was lubricated with 1 : 10,000 units heparin in normal saline. The four gas mixtures were supplied, one to each rabbit.

The temperature depression seen with 20 per cent carbon dioxide is greater than three-fold that seen with either pure air or oxygen (Table 1); the temperature depression with 20 per cent carbon dioxide is nearly doubled by prior pentobarbitone anæsthesia. The cooling rate with 20 per cent carbon dioxide and pentobarbitone anæsthesia is significantly faster, at the 0·1 per cent level (Table 2), than with pentobarbitone anæsthesia alone, but not proportionately so (Table 1)—this must be due to relative underventilation with increasing carbon dioxide accumulation during anæsthesia[2]. This contention is supported by the results obtained in a prior series of randomized experiments on 42 rabbits where chilling to 20° C rectal was effected with air, oxygen, and both 10 and 20 per cent carbon dioxide in both gases, during pentobarbitone anæsthesia with prior tracheotomy and simultaneous re-breathing (achieved by closing the expiratory value of the anæsthetic bag): in these 42 experiments the cooling rates were uniform.

The temperatures of cardiac arrest are uniform as are those of the onset of unconsciousness and the differences in cooling rate between the various groups are seen in the duration of the interval to unconsciousness (Table 1). While the differences in duration to cardiac arrest between those animals breathing oxygen as opposed to air (both with and without 20 per cent carbon dioxide and/or pentobarbitone anæsthesia) favour oxygen at the 5 per cent level of significance, the difference between those animals breathing air or oxygen with 20 per cent carbon dioxide, as opposed to those animals breathing air or oxygen under pentobarbitone anæsthesia, with or without carbon dioxide, favour 20 per cent carbon dioxide as opposed to pentobarbitone anæsthesia in terms of survival time at the 0·1 per cent level of significance (Table 2). These differences in survival times are presumably explained by the increased tissue oxygen uptake produced by high

Table 2

	No. of rabbits	Time to cardiac arrest (min)	Significance (analysis of variance) (%)
Oxygen/pentobarbitone 20% CO_2 in oxygen 20% CO_2 in oxygen/pentobarbitone	18	246·1	5·0

Significant linear cooling trends at 0·1 per cent level, with no evidence of curvature

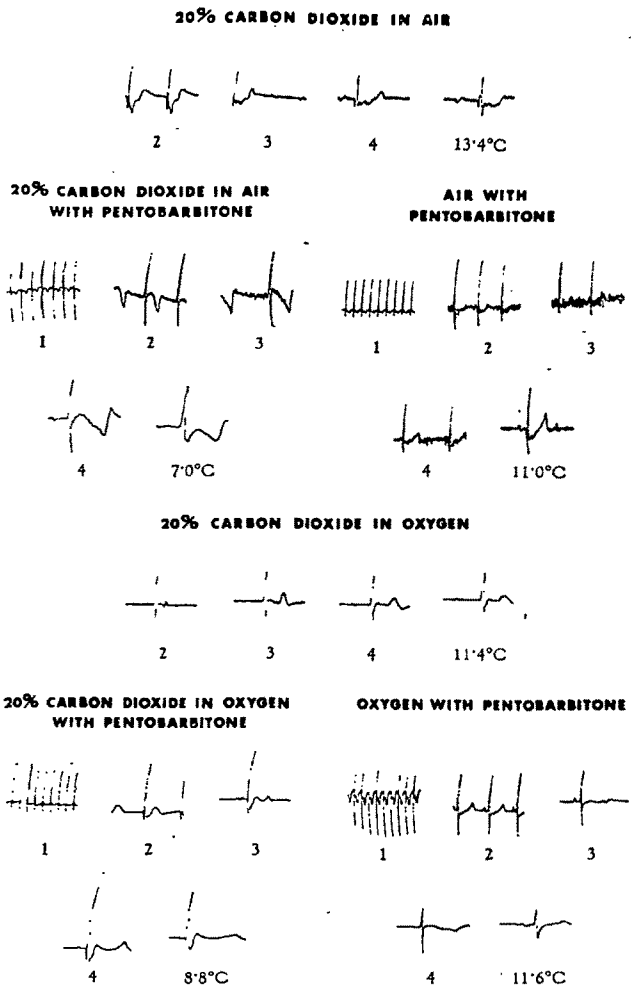

Fig. 1. The E.C.G. during hypothermia. 1, 38°–35° C; 2, 23°–20° C; 3, 18°–15° C; 4, 16°–12° C; 5, lowest actual temperature recorded. Each E.C.G. 'unit' occupies 2 sec of time-marker

levels of alveolar carbon dioxide concentration by the Bohr effect[3]. The lack of significance of the differences in the periods from unconsciousness to cardiac arrest is most reasonably ascribed to circulatory stasis after the onset of unconsciousness (Fig. 2) and minimal tissue oxygen uptake thereafter[4,5].

The electroencephalograph ceases at about 20° C when complete unconsciousness occurs, and spontaneous respirations usually cease at about 16° C—regardless of the presence or absence of 20 per cent carbon dioxide and/or pentobarbitone anæsthesia; the conjunctival reflex is also regularly present until about 16° C, when significant changes in the electrocardiograph start to occur and the blood pressure has fallen to below a quarter of its initial level (Fig. 2).

With adequate ventilation (note one animal 'died' at 24·8° C), the electrocardiograph is normal, except for an increasing bradycardia with gradual lengthening of the *PR* interval below about 25° C, until about 16° C, after which the *P* wave tends to diminish, the *ST* segment to become prolonged and either elevated or depressed, and the complex finally disrupts, to disappear at about 10° C (Fig. 1). The rhythm is regular while the configuration of the complex is preserved and an irregular rhythm presages impending dissolution of the complex. These changes in the electrocardiograph are dependent on temperature and not on the composition of the inspiratory gas mixture.

The role of an increased carbon dioxide tension of the blood in relation to cardiac arrhythmias during hypothermia is controversial, though there is plenty of evidence that hypercapnia is not in itself alone a cause of arrhythmias at normal temperatures[6–9] and recently evidence has been accruing to suggest that a raised carbon dioxide level, or a lowered blood *p*H, may actually delay the premature onset of arrhythmia during hypothermia[10] or facilitate the spontaneous reversion of arrhythmia occurring during hypothermia[11,12].

Earlier reports incriminating hypercapnia as a causative factor in the production of cardiac arrhythmia[13–15] may be criticized on the techniques used—excessive anæsthesia, the use of curare, and unduly rapid changes in inspiratory gas concentrations.

The observations of E.E.G., E.C.G., reflex activity and the maintenance of arterial pressure reported in this paper correspond with the reports of Smith[16], in the rabbit; Brendel *et al*[17] and Spohn *et al.*[18], in the dog; and Simpson[19] and Bryce-Smith *et al.*[20], in the monkey, during surface cooling by more conventional methods.

As already mentioned, a prior series of randomized experiments was performed on forty-two rabbits where chilling was stopped at 20° C rectal, at which temperature they were removed from the deep freeze. Of the first 19, in which spontaneous re-warming at room temperature was practised (18°–21° C), eight survived; and of the succeeding 23, in which re-warming was effected at 38° C ambient in an incubator, 17 survived. Survivors were killed after a fortnight, no disability having been observed. Thus, above cardiac arrest, survival was dependent on the rate of re-warming and not on the composition of the inspiratory gas mixture. Survival after chilling to 20° C rectal while inhaling 20 per cent carbon dioxide in air has been reported in the rabbit[21].

In the present series no survivals were obtained, though respiration was recommenced in two animals following cardiac arrest. The problem of survival after cardiac arrest in large mammals following surface cooling awaits solution[22], but success with small mammals[22] indicates that it is not insoluble.

The cooling rates reported here are significantly linear (at the 0·1 per cent level) above 20° C, to which temperature the reflexes, respiration and the blood pressure are maintained. The absence of any correlation of rates of body cooling with body weight, voluntary movement, shivering or anæsthetic dosage suggests that, in the absence of normal insulation (fur), the most important factor in

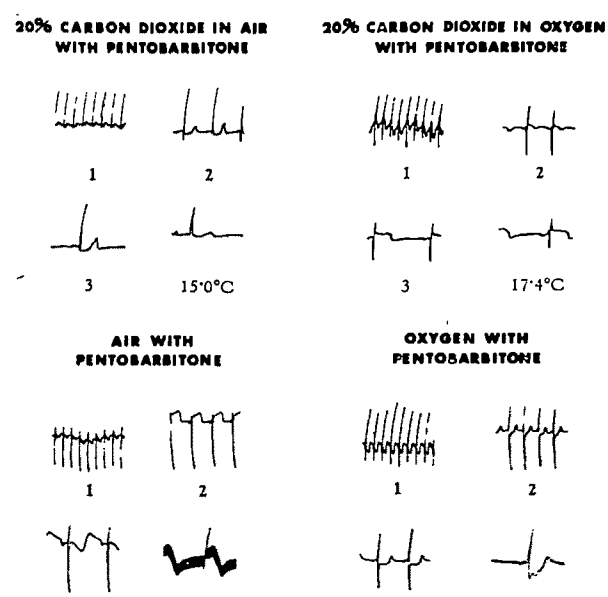

Fig. 2. Blood pressure and E.C.G. during hypothermia. 1, 38·8°–37·8° C; 2, 28·4°–24·4° C; 3, 20·6°–18·8° C; 4, lowest actual temperature recorded. Each E.C.G. 'unit' occupies 2 sec of time-marker. Arterial pressure; 1, 150–110 cm; 2, 120–100 cm; 3, 80–40 cm; 4, 40–20 cm

the depression of body temperature during surface cooling is the regulation of peripheral blood flow[23,24].

This work was carried out under the auspices of a Leverhulme Research Scholarship and thanks are due to the Clinical Research Committee of the Middlesex Hospital Medical School.

VARIATIONS IN X-RAY RESPONSE DURING THE DIVISION CYCLE OF PARTIALLY SYNCHRONIZED CHINESE HAMSTER CELLS IN CULTURE

By Dr. W. K. SINCLAIR and RICHARD A. MORTON

Division of Biological and Medical Research, Argonne National Laboratory, Argonne, Illinois

INVESTIGATIONS of the response to X-radiation at different stages of the division-cycle of mammalian cells grown *in vitro* can provide important evidence as to the nature of radiation damage. Terasima and Tolmach[1,2], in studies on various facets of the response to X-radiation of partially synchronized HeLa cells in culture, found two periods of resistance during the first cycle. The first resistance phase was associated with the pre-DNA synthetic period (G_1) and the second with the latter stages of the DNA synthetic period (S) or the early stages of the pre-mitotic period (G_2). In later work, these authors[3] and also Erikson and Szybalski[4] have used 5-fluorodeoxyuridine (FUDR) as an inhibitor of thymidylic acid synthesis to achieve synchrony in cultures. Both studies show that X-ray resistance increases as soon as DNA synthesis begins. All these studies were confined to the first division-cycle after synchronization.

We have examined, throughout two division cycles, the survival of partially synchronized Chinese hamster cells after a single dose of 750 r. of 250-kVp. X-radiation. The method of Terasima and Tolmach for separating dividing HeLa cells from cultures was found to be quite unsuccessful with our *V*-79 clone of Chinese hamster lung cells grown in *HUT*-15 medium[5]. The most successful of many methods tried was the following. Log phase cultures, grown overnight on plastic Petri dishes in a humid atmosphere of 2 per cent carbon dioxide and air at 37° C, were cooled to 4° C in the refrigerator for 1 h and then re-incubated for 2–6 h at 37° C. The medium was removed and 4 ml. of 0·03 per cent trypsin were added without rinsing. The plates were then rocked gently for 5 min on a wrist-action shaker. Trypsin was removed from the individual plates and pooled. This suspension had a high proportion of dividing cells, as estimated from stained sections; up to 75 per cent of the cells were in mitosis in some experiments. In experiments for which substantial numbers of cells were needed, about 45 per cent of the cells pooled from 30–40 plates were found to be in mitosis initially. The status of the remaining 55 per cent was uncertain, but, from the data to be shown here, it seems probable that many of these must have just divided and were therefore in quite close synchrony with those in mitosis.

The cooling of these cells provides only a slight pulse of mitosis in the base culture and no marked synchrony[6] was achieved. Cooling, however, was found essential to provide a better differential attachment between rounded up (dividing) cells and flattened out (non-dividing) cells.

Immediately after separation, the partially synchronized cell-population was inoculated into four groups of plates. The first and second group received about 15,000 cells per plate and were used for growth studies and tritiated thymidine labelling studies, respectively. The third set received approximately 1,000 cells per plate for exposure to X-radiation and the fourth group received 150–200 cells for plating efficiency estimation. All these plates were incubated within 30 min of adding trypsin. Time zero on the graphs, all which pertain to the same experiment, corresponds to the time at which incubation began.

In the growth study, plates were removed from the incubator at intervals, trypsinized for 15 min and the suspension counted at fixed settings on a Coulter counter. The growth curve is shown in Fig. 1*A*. The curve is essentially flat for the first 13·5 h, while in the next 5 h practically all the cells divide and the curve is flat again for approximately 8 h more before the second division begins. The generation time is about 13 h. The index of synchrony proposed by Blumenthal and Zaler[7] is:

$$F = \frac{N_2}{N_1} - 2^{t/g}$$

where N_1 is the number of cells at time t_1; N_2 is the number of cells at time t_2; t is the time interval t_2–t_1; and g is the generation time. This index is 0 for log growth, +1 for doubling in zero time and −1 for periods of no cell doubling. For synchrony, positive values should be found at division followed by negative values in the next part of the cycle. For the data of Fig. 1*A*, F has a value close to −1·0 for the first 13·5 h, followed by $F = +0{\cdot}58$ while the cells are dividing (t_1 = 13·5 h, N_1 = 16,500 cells; t_2 = 18·5 h, N_2 = 31,000 cells). Thereafter, F is clearly negative again until the next division begins. The highest value found for F during the division period, in any of our experiments, was + 0·81. The actual number of cells found in the first cycle is consistent with our other data. For this experiment 45 per cent of the cells were

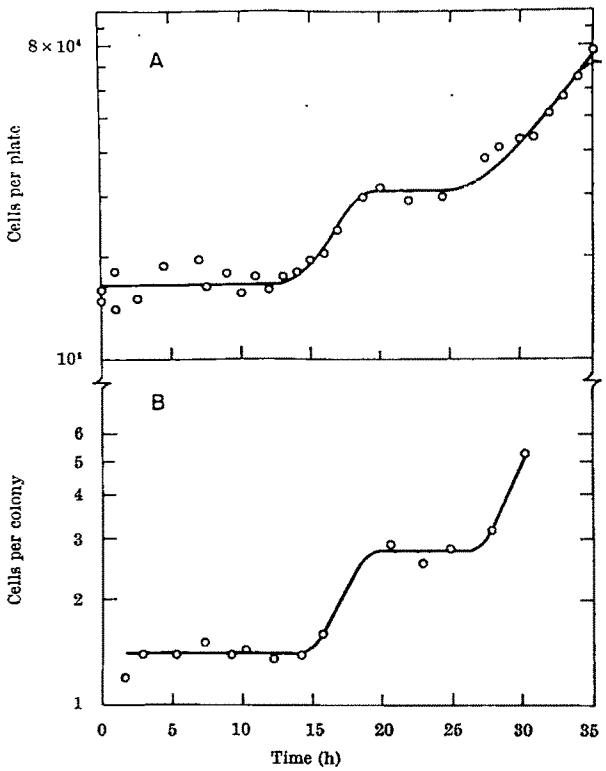

Fig. 1. (*A*) Growth of cells per plate measured by counting trypsinized cells on Coulter counter (Exp. *S*-3); (*B*) cells per colony as a function of time, measured from stained labelled plates (Exp. *S*-3)

in mitosis and would give two cells each after division. A total of (45 per cent × 2) + 55 per cent = 145 per cent of the initial number plated would be expected if all cells survived. A plating efficiency of 63 per cent (found from the fourth series of plates) would reduce this to 91 per cent if the non-survivors fail to attach and the plating efficiency is the same for both mitotic and non-mitotic cells. The actual value found was about 100 per cent.

For the labelling studies, 1 μc. of H^3-thymidine (3 c./mM) was added to the medium of the plates. The plates were incubated for ½ h at 37° C. All subsequent operations were carried out without removing the cells from the plates. The medium was poured off and the cells washed with buffered saline and fixed in acetic alcohol. Later, liquid nuclear emulsion was added in a thin layer. After about 4 weeks of exposure at 4° C to tritium β-particles the plates were developed at 18° C and stained with hæmatoxylin and eosin. These plates were assayed for cells per colony and percentage of labelled cells.

A plot of cells per colony obtained from the stained plates is shown in Fig. 1*B*. The ratio is constant during the first cycle at about 1·4. Since the 45 per cent mitotic cells provide a two-cell clone very soon after attachment, the expected average value of cells/clone is 1·45 if no more cells divide. It rises at division to twice this, ~ 2·8, and then remains constant in the second cycle until the next division begins. For this curve F = + 0·68 during division, which is somewhat higher than for Fig. 1*A*. As an indication of synchrony, this method, using directly stained plates, may be preferable to counting dilute cell suspensions on the Coulter counter.

The percentage of cells labelled at various times by the pulse of tritiated thymidine was assayed by examining at least 100 cells on each plate. An arbitrary limit of more than 12 grains per nucleus, found from grain counts on unlabelled plates, was taken as the criterion of a labelled cell. It was not often necessary to apply this criterion. The result, as a function of time, is shown in Fig. 2*A*. The percentage of labelled cells rises to 100 after about 9 h and then falls to zero at ~ 15 h, when mitosis is high. The rise and fall is repeated, possibly a little earlier, in the next cycle. The average S period, measured from 50 per cent on the ascending part of the curve to 50 per cent on the descending part of the curve of Fig. 2*A*, is about 6·5 h or one-half the cycle, in agreement with investigations on another line of Chinese hamster cells by Hsu, Dewey and Humphrey[8].

For radiation studies, duplicate plates from the third series were exposed at intervals to 750 r. (710 rads) of 250-kVp. X-radiation (half value layer = 0·9 mm copper, 100 rads/min). After 12 days of incubation the plates were stained with methylene blue and colonies counted. The normal surviving fraction of an asynchronous Chinese hamster population at this dose is about 0·12 and this is well beyond the shoulder region of the survival curves[5]. The number of cells surviving exposure at different times, expressed as a fraction of the controls, is shown in Fig. 2*B*. Survival ranges from about 0·1 initially to 0·31 at 9–10 h, only to fall again to about 0·1 at 14 h as division begins. This variation is repeated at a higher level, because of cell doubling, with approximately the same time relationships, in the next cycle. The peak of survival correlates closely with the peak of pulse-labelled cells but may follow it up to 1 h. The cells thus appear most resistant when synthesizing DNA. In a repeat experiment with the same percentage of mitosis in the stained section, very similar results were obtained, with maximum labelling preceding maximum resistance by about 1 h. Results of poorer resolution, but nevertheless exhibiting the same time relationships and correlation between DNA synthesis and survival, have been obtained in several experiments in which lower initial fractions of mitotic cells were available.

Other work has shown a close association of resistance to X-radiation and the onset of DNA synthesis. Studies with inhibitors of DNA synthesis, such as FUDR, in Detroit 98 cells[4] and HeLa cells[3] indicate an increase in resistance when the block is removed and DNA synthesis is resumed. In our case, maximum X-ray resistance

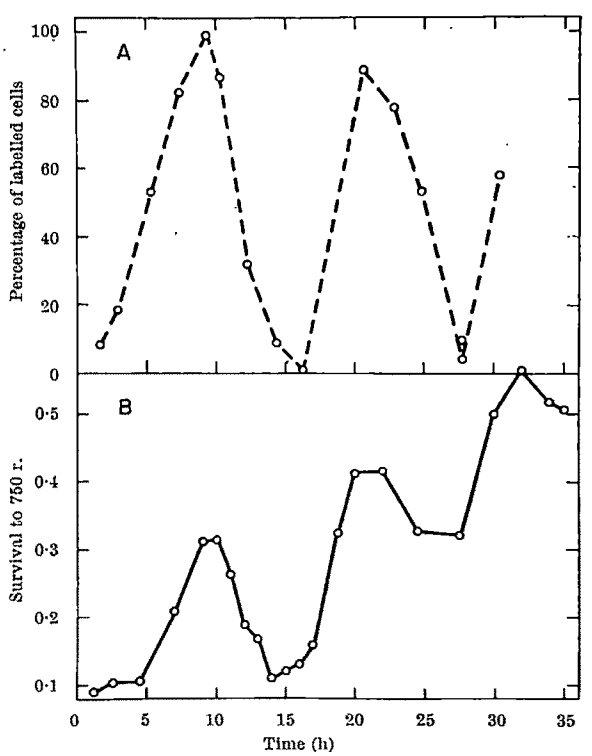

Fig. 2. (*A*) Percentage of cells labelled with tritiated thymidine as a function of time (Exp. *S*-3)0 (*B*) radiation survival to a single dose of 750 r. (710 rads) as a function of time (Exp. *S*-3)

appears to coincide almost exactly with the period of maximum labelling. An appreciable lag between these maxima, however, was reported for HeLa cells[2]. Such a lag may arise from growth differences between irradiated plates and labelled plates if the cell concentration is different. We do not know whether these effects were present in the experiments reported for HeLa cells, but our investigations on asynchronous Chinese hamster cells indicate that at concentrations of 1,000 and 15,000 cells per plate, growth differences, if any, are small. The sharp fall in resistance in the G_2 period (Fig. 2*B*) is consistent with the data of Hsu, Dewey and Humphrey[8]. They found, by ^{3}H-thymidine labelling of asynchronous Chinese hamster cells, 3–4 times less γ-ray induced chromosome damage for cells in *S* phase than for cells in G_2 phase. This would agree with our observations if chromosome damage is correlated with cell death. Different results were found by Dewey and Humphrey[9] in other cell lines. Finally, we observe only one peak of resistance in the cycle, during DNA synthesis, and none during the G_1 phase, as in the case of HeLa cells[2]. The studies with HeLa were limited to the first cycle following inoculation, in which there may be attachment problems. On the other hand, these hamster cells have such a short G_1 period that differences during this period for the two cell lines may not be unreasonable.

The survival to a single dose (Fig. 2*B*) does not determine the lethal response uniquely. However, the data for 750 r. given in Fig. 2*B* are consistent with the survival found for the asynchronous hamster population at this dose. Taking the area under the curve for a linear plot of the data of Fig. 2*B*, the average survival over the first 15 h, for cells with a multiplicity of 1·45 (cells per clone), is found to be 0·177. For single cells in an asynchronous population, the survival fraction at 750 r. should be $\frac{0{\cdot}177}{1{\cdot}45} = 0{\cdot}12$, which is the value actually found experimentally[5]. Full survival curves at different times will be necessary to compare the complete radiation responses of the various stages of the division cycle and correlate these with results for the asynchronous hamster population.

CHOLINESTERASE-CONTAINING SYSTEMS OF THE BRAIN OF THE RAT

By Dr. C. C. D. SHUTE and Dr. P. R. LEWIS
Department of Anatomy, University of Cambridge

THE thiocholine technique for the histochemical localization of cholinesterases, as originally applied to the rat brain by Koelle[1], showed a bewilderingly wide distribution of enzyme. Further investigations by ourselves have indicated that the pattern of cholinesterase activity varies in different areas[2,3]. In the forebrain these areas can be classified as follows: (*a*) those where the enzyme is intracytoplasmic, and causes the cell bodies of cholinesterase-containing neurones to stand out clearly from the surrounding grey matter, as in the subthalamus, globus pallidus, lateral preoptic area, diagonal band and medial septal nucleus; (*b*) those where the enzyme is intra-axonal, with the consequence that the cholinesterase-containing fibres can be readily distinguished from adjacent white matter, as in the dorsal fornix, fimbria, fasciculus retroflexus and ventral supraoptic decussation; (*c*) those where the staining is so dense that the precise location of enzyme is difficult to determine, as in the caudate-putamen, nucleus accumbens, pars ventralis of the lateral amygdaloid nucleus, and nucleus of the lateral olfactory tract.

Areas with generalized staining rather less dense than the foregoing include the midline and intralaminar thalamic nuclei, the ventral nucleus of the lateral geniculate body and the pretectal nuclei. In addition, one can recognize: (*d*) areas where the enzyme is in specific laminæ, as in the cingulate gyrus, which contains cholinesterase mainly in layers i and iii, the hippocampus where the enzyme is located on either side of the pyramidal layer and in the stratum lacunosum, the dentate gyrus with enzyme on either side of the granular layer, and the olfactory bulb, which contains enzyme in the glomerular and mitral cell layers; and (*e*) areas, lightly stained by the thiocholine method, where the distribution of cholinesterase appears to be diffuse, as in most regions of the neocortex. Certain areas of the brain show no evidence of cholinesterase activity: for example, the white matter of the internal capsule and of the cerebral peduncle, and the commissural fibres of the corpus callosum.

In order to clarify the picture in neurological terms, we adopted the device of placing lesions in selected areas of the brain and allowing the animal to survive for four days or more[4]. In this way we were able to show that interruption of cholinesterase-containing axons causes enzyme to pile up for a short distance on the cell body side of the cut and to disappear on the opposite side from the whole length of the severed fibres, including their terminals. The method, therefore, enabled us to determine the polarity and distribution of cholinesterase-containing tracts, which was often in doubt in normal material. We have since refined our technique by using radiofrequency current to produce thermal lesions accurately placed by means of a stereotaxic instrument[5]. In this way we have been able to interrupt cholinesterase-containing fibres with minimal damage to surrounding structures, and so build up a complete map of all such pathways in the forebrain (Fig. 1).

We have found that cholinesterase-containing fibres ascend from the brain stem into the forebrain by two main routes, which we propose to call the 'dorsal' and 'ventral tegmental pathways'. The dorsal tegmental pathway extends rostrally from the region of the nucleus cuneiformis of the mesencephalic tegmentum and projects on the pretectal area, the geniculate bodies, the mammillary region and the thalamus. In animals which have been subjected to a unilateral midbrain lesion involving this pathway and later killed, there is a loss of staining on the operated side which is particularly marked in certain nuclei to which the dorsal tegmental pathway contributes a dense terminal neuropil, namely, the pretectal nuclei (especially the nucleus pretectalis profundus), the parafascicular-centromedian nucleus, the intralaminar thalamic nuclei and the anterior thalamic nuclei.. The dorsal tegmental projection does not appear to reach cortical levels.

The ventral tegmental pathway extends rostrally through the substantia nigra and the region of the ventral tegmental nucleus to enter the subthalamic H_2 field and

the lateral hypothalamic area of the diencephalon. Some fibres which pierce the descending tracts of the basis pedunculi helps to form the so-called 'comb bundle'. In normal material, bundles belonging to the ventral tegmental pathway can be traced through the diencephalon as far as the globus pallidus: they correspond to the nigrostrial fibres of previous accounts[6]. In animals which have been subjected to a unilateral lesion of the ventral tegmental pathway at the level of the midbrain-diencephalic junction, these bundles lose their staining on the operated side, and there is an appreciable ipsilateral pallor of the normally densely stained neuropil of the caudate-putamen.

All cortical areas receive a projection of cholinesterase-containing fibres, which accounts for the loss of staining seen when these areas are denervated. We have found it convenient to group the corticopetal projections into five radiations, which we designate 'striatal', 'olfactory', 'amygdaloid', 'cingulate' and 'septal'. Fibres of the striatal radiation run in the external capsule (Fig. 2) and are distributed to the middle part of the lateral hemispheral cortex, extending as far down as the rhinal fissure. They reach the external capsule by traversing the caudate-putamen in company with cholinesterase-free bundles connecting the cortex with the internal capsule. Many apparently arise from cholinesterase-containing cells scattered throughout the globus pallidus and to a lesser extent in the caudate-putamen; others may have a more caudal origin from the ventral tegmental pathway. Lesions of the globus pallidus cause loss of fibre staining in the external capsule. The olfactory radiation can be traced from the lateral preoptic area and the olfactory tubercle, which include many cholinesterase-containing neurones, into the olfactory stalk and lateral olfactory tract, and from there to the prepyriform cortex and to the glomerular and mitral cell layers of the olfactory bulb. The normal staining of these layers is diminished by lesions involving the olfactory radiation. The amygdaloid radiation is continuous with the striatal radiation dorsally and the olfactory radiation anteriorly; its fibres pass from the lateral preoptic area through the amygdaloid, and are distributed via the lower part of the external capsule to postpyriform or entorhinal cortex. The cingulate radiation arches upwards in the bundle of Zuckerkandl in front of the genu of the corpus callosum, and travels back in the cingulum to supply superolateral and cingulate cortex. Finally, cholinesterase-containing cells of the diagonal band and medial septal nuclei give rise to fibres of the septal radiation, which is distributed to the hippocampus and dentate gyrus via the supracallosal striæ, dorsal fornix, alveus and fimbria (Fig. 3). Lesions of the septal radiation cause disappearance of the banded staining normally seen in the hippocampal formation (Fig. 4). This observation contradicts previous suggestions that afferent fibres in the fornix terminate only in the presubiculum[7] or in the dentate gyrus[8].

A portion of the septal radiation projects subcortically to two of the regions of the brain where the blood-brain

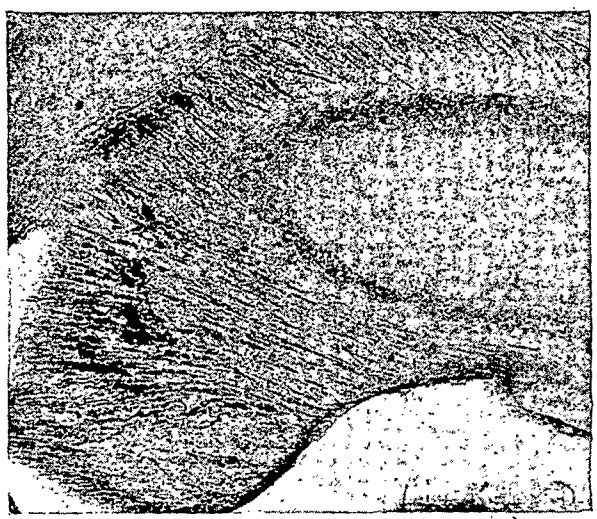

Fig. 3. Enzymatic pile-up in fibres of the alveus and fimbria. (×c. 26)

barrier is deficient, namely, the subfornical organ, otherwise known as the intercolumnar tubercle, and the supraoptic crest. The cholinesterase-containing fibres which innervate these organs arise from cells situated in the midline region of the septum, in the substance of the hippocampal commissure, and in the dorsal fornix.

We have also investigated experimentally a number of other subcortical pathways which carry cholinesterase-containing fibres. Those travelling with the 'fasciculus retroflexus' project on the interpeduncular nucleus. Fibres in the substance of the stria terminalis and at its lateral border, which we term the 'lateral strial bundle', project caudally, that is, against the main stream of the stria, and constitute a roundabout route from the lateral preoptic area to the amygdaloid. There is another group of fibres, on the medial side of the stria terminalis but not really part of it, which we have called the 'medial strial bundle': this projects on to the lateral geniculate body, especially on its more deeply staining ventral nucleus. The 'ventral supraoptic decussation' projects on to the pretectal area and superior colliculus. Interruption of the dorsal tegmental pathway produces loss of staining of the ascending fibres of the decussation, that is, those travelling forwards to the region of the optic chiasma. The medial strial bundle and the ventral supraoptic decussation can both be interpreted as aberrant loops of the dorsal tegmental pathway: the former an uncrossed bundle, and the latter a crossed one.

It is tempting to regard the cortical and sub-cortical pathways described here as part of a unified system, in which they represent the forebrain continuation of the brain stem reticular formation. This also consists, mainly if not entirely, of neurones rich in cholinesterase. The dorsal and ventral tegmental pathways correspond closely to the thalamic and extrathalamic portions respectively of the ascending reticular activating system described in cat by Starzl, Taylor and Magoun[9]. The problem remains as to whether these pathways, in view of their high concentration of cholinesterase, can be properly described as cholinergic. de Robertis *et al.*[10,11] have shown in homogenates of rat brain that acetylcholinesterase, acetylcholine and cholinacetylase are concentrated in subfractions containing nerve endings and synaptic vesicles. The association thus obtained between the three substances known to characterize cholinergic neurones in the peripheral nervous system would appear to justify the assumption that, in the central nervous system too, acetylcholinesterase is produced by cholinergic neurones and released at their endings.

For this reason we have thought it desirable to investigate the contribution to total staining made by true cholinesterase (AcChE) and pseudocholinesterase (ChE) in our material. Sections of normal brain were incubated in substrate solutions containing acetyl, butyryl and propionyl thiocholine, with and without the selective AcChE inhibitor (62*C*47) and ChE inhibitor (ethopropazine) recommended for rat brain by Bayliss and Todrick[12]. Comparison of the intensity of staining obtained with acetyl and propionyl substrates in the presence of ChE inhibitor indicated that the AcChE of rat brain hydrolyses propionyl thiocholine almost as effectively as acetyl thiocholine. On the other hand, there is no visible evidence of hydrolysis of butyryl thiocholine by AcChE even after long incubation: this is borne out by the fact that addition of AcChE inhibitor to Bu substrate did not affect the staining. Bayliss and Todrick[12] estimated that, when AcChE and ChE are both present, the contribution of AcChE to the total hydrolysis of butyrylcholine is 9 per cent. An indication of the substrate affinity of ChE is given by the intensity of staining of cerebral blood vessels (although we have found that certain blood vessels, especially those in the midline thalamic and cingulate regions, contain some AcChE). On this basis it

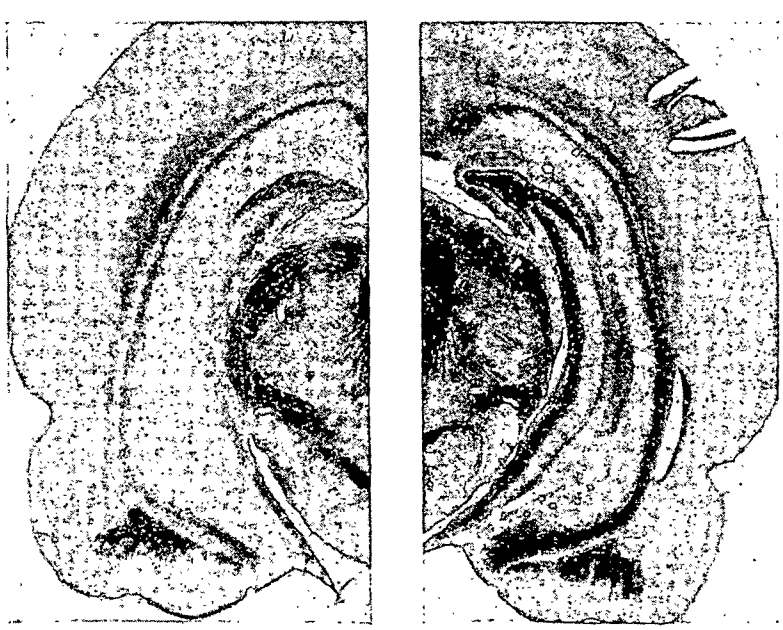

Fig. 4. Loss of staining in the hippocampus and dentate gyrus of the operated side 7 days after a fimbrial lesion. (×c. 9)

Fig. 5. Loss of staining around the motoneurones of the oculomotor nucleus 20 days after a lesion of the ventral tegmental nucleus. The nucleus of Edinger–Westphal is unaffected. (×c. 83)

may be said that ChE in rat brain hydrolyses propionyl thiocholine rather more effectively and acetyl thiocholine less effectively than butyryl thiocholine.

We have so far had no opportunity to study the hydrolysis of benzoyl thiocholine. Such an investigation would be of interest since the ability to hydrolyse benzoylcholine was used by Burgen and Chipman[13] as a criterion for the distribution of what they term ChE II in dog brain. Their findings do not tally with the localization of ChE in rat brain, as determined by us with the use of inhibitors: for example, we detected no ChE in the caudate. The discrepancy in the distribution of these enzymes may be due to lack of substrate specificity, since it has been shown that when AcChE and ChE are both present 30 per cent of the total hydrolysis of benzoylcholine is caused by AcChE[12]. Certainly our histochemical findings are consistent with the results obtained by Bayliss and Todrick using biochemical methods.

We conclude that two types of cholinesterase-containing neurones occur in rat brain: those which contain AcChE only, and those which contain ChE with or without some AcChE also present. Our findings in this respect run counter to those of previous workers, who have mostly held that central nervous ChE was located almost entirely in blood vessels and glia[14]. In the forebrain, the exclusively AcChE-containing neurones are those associated with the ventral tegmental pathway. They include the projections to the subfornical organ and supraoptic crest, and the radiations to the hippocampal formation, neocortex, olfactory cortex and the olfactory bulb described here, and also the dense neuropil of certain subcortical nuclei which appear to be associated with these radiations, that is, that of the caudate-putamen, the nucleus accumbens, the pars ventralis of the lateral nucleus of the amygdaloid, and the nucleus of the lateral olfactory tract. The ChE-containing neurones include those of the dorsal tegmental pathway, which project to the thalamus and contribute a dense neuropil to its midline and intralaminar nuclei, and also to the anteroventral thalamic nucleus. Other ChE-containing neurones of the forebrain are as follows: (1) the interstitial nucleus of the ventral hippocampal commissure—the neurones which constitute this nucleus can be seen in our material to project to the medial cortex of the frontal lobe; (2) the islets of Calleja, which project on to the superficial layer of the olfactory tubercle; (3) the anterior thalamic nuclei, whose projection on to layers i and iii of the cingulate gyrus is superimposed on the exclusively AcChE-containing projection of the cingulate radiation; (4) some cells of the lateral thalamic nucleus; (5) the nucleus reuniens of the thalamus, which possibly projects to the anterior cingulate cortex[15]; (6) the interstitial nucleus of the ventral supraoptic decussation, which contributes to the projection of that bundle on to the pretectal and tectal regions; (7) a few cells of the medial habenular nucleus, projecting on to the nucleus interpeduncularis.

In the brain stem the areas of grey matter which possess intracellular cholinesterase include the motor nuclei of cranial nerves, some cells of the sensory trigeminal nucleus, the lateral and superior vestibular nuclei, the red nucleus, the tegmental nuclei, nuclei of the reticular formation and cells of the stratum griseum profundum of the superior colliculus. As in the forebrain, it is possible to distinguish sites containing AcChE only and those in which the enzyme is partly ChE. Thus, the cells of the branchiomotor nuclei of cranial nerves V and VII and of the nucleus ambiguus contain AcChE only. The somatic motor nuclei of cranial nerves III, IV, VI and XII also contain AcChE only, with the exception of a group of cells forming the ventral portion of the hypoglossal nucleus in its caudal half. The AcChE of the somatic and branchiomotor nuclei is located not only within cell bodies but also in surrounding neuropil. We have been able to eliminate staining of pericellular neuropil in the oculomotor nucleus of one side by placing a lesion in the ipsilateral ventral tegmental nucleus (Fig. 5). This finding suggests that the neuropil is formed by presynaptic terminals of cholinesterase-containing neurones projecting on to the motor cells.

Of the visceral motor nuclei, the nucleus of Edinger-Westphal and the dorsal motor nucleus of the vagus possess a high concentration of intracellular ChE. The so-called interstitial nucleus of the ventral tegmental decussation also contains intracellular ChE, and appearances in normal material suggest that it may project on to the Edinger-Westphal nucleus and on to the deep pretectal nucleus. Unlike those of the visceral motor nuclei of III and X, the cells identified by us as belonging to the salivatory nucleus[2,16] contain only AcChE. The same is true of the preolivary nucleus and retro-olivary cells believed to be the source of the olivocochlear bundle of Rasmussen[17]. The nucleus coeruleus, sometimes described as the small-celled component of the mesencephalic trigeminal nucleus, also contains only AcChE and appears to send fibres to the cerebellum. ChE is distributed in other brain stem nuclei as follows: (1) the nucleus cuneiformis of the midbrain tegmentum, which appears to be, in part at least, the origin of the dorsal tegmental pathway; (2) the dorsal and deep tegmental nuclei (these nuclei appear to project to various centres which also contain ChE, for example, the nucleus cuneiformis, part of the interpeduncular nucleus, the superior and lateral vestibular nuclei via the dorsal longitudinal fasciculus, and the nucleus reticularis tegmenti pontis which relays to the cerebellum); (3) the nucleus reticularis pontis oralis et caudalis and the nucleus reticularis lateralis; (4) cells of the stratum griseum profundum of the optic tectum which appear to project on the superficial layer of the tectum. Our interpretation of the course taken by ChE-containing neurones in the brain stem, other than those of the dorsal tegmental pathway projecting on the thalamus, must be regarded as provisional only, since so far we have not placed experimental lesions caudal to the midbrain tegmentum.

The functional significance of intraneuronal ChE is at present obscure. In the absence of any evidence to the contrary, it seems reasonable to assume that neurones which contain AcChE only in high concentration, such as those forming the corticopetal radiations described in this article, are cholinergic, that is, operate by the release of acetylcholine. The likelihood that the cerebral cortex does come under cholinergic influences is enhanced by the finding that cortical cells are excited by acetylcholine[18]. Most of the ChE-containing neurones in the rat brain—the anterodorsal nucleus of the thalamus is an exception—also contain a high concentration of AcChE, and may

likewise be cholinergic. Thus the thalamus, which we have shown to contain ChE within the cell bodies of neurones belonging to the anterior group of nuclei and in nerve terminals derived from the dorsal tegmental pathway, has been found in dog to be rich in acetylcholine[19] and in cholinacetylase[20]. It has been suggested that ChE may act at sites of constant ACh production to prevent the concentration of ACh from passing beyond a certain level[21]: since ChE does not exhibit the phenomenon of substrate inhibition with respect to acetylcholine, it continues to act at concentrations of the latter which would inhibit AcChE. Another possibility is that the *in vivo* action of ChE is on higher choline or related esters. Koelle[22] has argued that the ChE which is present in large quantities in addition to AcChE in Auerbach's plexus may be concerned with the hydrolysis of such esters acting as local hormones or transmitting agents in the gut. These esters might act directly on the receptor or might have a potentiating effect, just as butyrylcholine will not only cause contraction of frog's rectus but will also sensitize the muscle to the action of acetylcholine[23]. It is not certain, however, that higher cholinesters occur in normal brain[24], other than γ-aminobutyrylcholine, which may function as an inhibitory transmitter[25].

Other sites of acetylcholine activity where ChE is present in addition to AcChE include the motor end plates of rat diaphragm[26]. We have studied the cholinesterase content of motor end plates in the tongue musculature of rat, and our observations suggest that the proportion of ChE is greatest in those of the intrinsic muscles. It is noteworthy that these muscles are believed to be innervated from the ventral part of the hypoglossal nucleus[27], which we have found to contain intraneuronal ChE. The other location for ChE in the medullary portion of the floor of the fourth ventricle is in the cells which form the dorsal motor nucleus of the vagus. These neurones are generally held to be cholinergic, although the evidence, based mainly on the acetylcholine content of the cervical vagal trunk[19], is not conclusive since some at least of the cholinergic fibres in the cervical vagus are probably derived from the sympathetic system[28].

Some importance may be attached to the distributional pattern of intraneuronal ChE in the central nervous system. It is noticeable, for example, that a number of the sites in which this enzyme is concentrated, such as the interstitial nucleus of the hippocampal commissure, the dorsal and deep tegmental nuclei, and the anterior thalamic nuclei, are on projection pathways related to the hippocampal fornix system. Other nuclei containing intracellular ChE, for example, the nucleus reticularis tegmenti pontis[29] and the nucleus reticularis lateralis[30], are known to project on to the cerebellum. Green and Morin[31] found electrophysiological evidence, which they were not then able to explain, for a functional relationship between fornix pathways and the cerebellar cortex. The projection of ChE-containing neurones on to the midline and intralaminar thalamic nuclei must, of course, be considered in relation to the diffuse thalamic projection system of Morison and Dempsey[32] which originates from these nuclei. It is significant, therefore, that high-frequency repetitive stimulation of the midline and intralaminar nuclei produces electrocortical arousal[33], and that a similar effect can be achieved by intra-arterial injection of ChE inhibitor[34]. Certain of the midline and intralaminar nuclei have been shown to project to the corpus striatum[35], and the final link with the cortex responsible for bringing about the arousal reaction may be achieved through the corticopetal projections of the AChE-containing, presumed cholinergic cells which we have found in this region.

RESEMBLANCES BETWEEN PASSIVE ANAPHYLACTIC SENSITIZATION AND TRANSMISSION OF PASSIVE IMMUNITY

By Prof. F. W. R. BRAMBELL, F.R.S.

Agricultural Research Council's Unit of Embryology, Department of Zoology, University College of North Wales, Bangor

RECENT advances in knowledge of passive anaphylactic sensitization and of transmission of passive immunity from mother to young have disclosed certain similarities in these two processes which it would seem worthwhile to consider, since it is possible that too little attention has been paid by those engaged in the one field to the results obtained in the other.

Hartley[1] was the first to suspect a similarity between the transmission of passive immunity from mother to fœtus and passive anaphylactic sensitization in guinea pigs and

to suggest that both processes depended on the acceptability of the antibody molecules to the cells. He knew that guinea pigs could be readily sensitized by antitoxins prepared in guinea pigs, rabbits or man, but not by those prepared in horses, oxen, sheep, goats or pigs. He showed that whereas guinea pig antitoxin was transmitted readily from mother to fœtus, horse antitoxin was scarcely transmitted at all. Further, he showed[2] that diphtheria antitoxin prepared in a guinea pig, when pepsin refined, lost the capacity both for passive sensitization and for passive transmission, although retaining its antibody activity.

During the past ten years much additional evidence has been obtained which tends to justify Hartley's assumption. To these advances, increasing knowledge of the structure of the γ-globulin molecule has contributed notably. It is unfortunate, however, that whereas most of the work on anaphylaxis has been on the guinea pig, most of that on the transmission of passive immunity has been on the rabbit, rat and mouse. Parallel studies on both these phenomena in a single species are needed for precise comparison and they should be rewarding.

Anaphylactic sensitization of guinea pigs *in vivo* and of guinea pig tissues *in vitro* is a selective process in so far as γ-globulin is the only effective agent, and the γ-globulins of some species are more effective than those of others. Humphrey and Mota[3] found, for example, that guinea pig and rabbit antibodies are the most effective, monkey, dog and human antibodies somewhat less effective, and rat, horse, goat and fowl antibodies ineffective. Antibodies from oxen and sheep are ineffective also[1], as are human auto-immune antibodies[3] and those to pollen[4].

Immunity is transmitted before birth in the rabbit and guinea pig and mainly after birth in the rat and the mouse; the γ-globulin being transmitted preferentially to the other serum proteins in all these animals. Antitoxins prepared in various species are transmitted preferentially in the order rabbit > human > guinea pig > dog > horse > ox in the rabbit. Rabbit antitoxins are transmitted in quantities about 100 times those of bovine antitoxins[5]. Rabbit, rat, guinea pig and other rodent antibodies are transmitted readily from the gut to the circulation in the suckling rat, but hyperimmune agglutinins to *Salmonella pullorum* from these species are transmitted several times more readily than agglutinins to *Brucella abortus* prepared in the same species[6]. Antibodies prepared in ox, sheep and fowl are not transmitted[7,8]. Some antibodies are transmitted preferentially in the order mouse > rat > guinea pig > rabbit > ox in the mouse[9,10]. However, when hyperimmune rabbit anti-*Brucella* serum containing a high titre of complete agglutinins is fed to suckling rats and mice a considerable quantity of incomplete agglutinins, with little or no complete agglutinins, appears in the circulation. Thus there is a notable similarity between passive anaphylactic sensitization and passive transmission of immunity in that both processes are selective between immune globulins derived from different species as well as in some cases between different antibodies derived from the same species.

Hartley[2] was the first to observe that diphtheria antitoxin prepared in guinea pigs, when pepsin refined, lost both the properties of passive sensitization of guinea pig smooth muscle tissue *in vivo* and *in vitro*, and of passive transmission from the maternal to the fœtal circulations in this species, although retaining unimpaired its antibody activity. The rate of transmission across the rabbit fœtal membranes of homologous diphtheria antitoxin is much reduced by pepsin refining[11]. Pepsin refining reduces the size of the antitoxin molecule by about one-third without impairing its antibody activity but with loss of most of its antigenicity. This suggested that the part of the molecule destroyed by pepsin was that responsible for anaphylactic sensitization and for the rate of transmission across the fœtal membranes. This part of the molecule also appears to be that which carries most of the antigenic determinants which distinguish the γ-globulin of one species from that of another. The discovery at this time[12] that the parts of rabbit γ-globulin molecules lost by pepsin digestion could be recovered after digestion with crystalline papain and separated chromatographically in a crystallizable state opened up the way for testing this hypothesis. This technique yielded also two fractions with antibody activity, each of which consisted of molecular fragments of about one-half the size of the product of pepsin digestion. Each fraction had incomplete or monovalent antibody activity as distinct from the complete or divalent activity of pepsinized antitoxin. These fractions were called I and II and the antigenic fraction was called III. It has been shown since[13] that a molecule of rabbit γ_1-globulin is composed of two identical pieces of fraction I together with one piece of fraction III, and that the molecule of rabbit γ_2-globulin is similarly constructed of two pieces of fraction II and one of fraction III. It has been shown[14,15] that neither fraction I nor fraction II of rabbit antibody is able to sensitize the skin of the guinea pig either for direct or reversed passive cutaneous anaphylaxis, whereas fraction III is an effective sensitizing agent in reversed passive cutaneous anaphylaxis. It was concluded that whereas guinea pig cells could readily fix fraction III, they could not fix fractions I or II of rabbit γ-globulin. Fraction III of rabbit γ-globulin, isotopically labelled with iodine-131, is transmitted across the membranes to the fœtal circulation of the rabbit eleven times as readily as fraction I and six times as readily as fraction II[16]. Fraction III was transmitted at nearly the rate (0·7) of whole rabbit γ-globulin similarly labelled. This suggested that the region of the γ-globulin molecule which contains the 'recognition unit' for transmission by homologous cells is also that (fraction III) which contains most of the antigenic groups for heterologous cells. The close correspondence of the conclusions that have been drawn from the use of these molecular fragments in passive anaphylactic sensitization and in the transmission of passive immunity is obvious.

Non-immune serum can interfere with the passive sensitization of guinea pig tissues by antibodies[17]. This interference is due to the γ-globulin fraction of the serum, not to the other serum proteins[18]. It can be demonstrated *in vivo* in passive general anaphylaxis in both guinea pigs and mice[19], and in passive cutaneous anaphylaxis in guinea pigs[20]. It can be demonstrated *in vitro* in guinea pig tissues by the Schultz–Dale reaction of smooth muscle[3,21] by histamine release from chopped lung[22] and by mast cell degranulation[3]. The γ-globulins of different species vary in their capacity to inhibit passive sensitization in guinea pigs; for example, the effectiveness of γ-globulins to interfere with the sensitization by rabbit antibodies of guinea pig smooth muscle tissue decreases in the order rabbit > man > dog > guinea pig > rat > horse > ox > pig > fowl > goat[23]. For complete inhibition of sensitization the non-specific γ-globulin must be present in amounts considerably in excess of the antibody, thus for inhibition of passive cutaneous sensitization in the guinea pig by rabbit antibody a ratio of antibody/non-specific γ-globulin of 1 : 100 is required[21]. Fraction III of the papain hydrolysed rabbit γ-globulin is even more effective than the whole γ-globulin in inhibiting the sensitization of guinea pig tissues by rabbit antibody, whereas fraction I is entirely without effect[15].

Certain heterologous sera interfere with the transmission of antibodies from the gut to the circulation of suckling mice and rats when administered orally at the same time[24]. The transmission of both homologous and heterologous antibodies can be interfered with in this way, but only the sera of certain species interfere. Rat, mouse, hamster and sheep sera do not interfere with the transmission of antibodies in either the suckling mouse or suckling rat. Rabbit, guinea pig, human and bovine

sera are effective in producing interference in both rats and mice; all do so about equally in the rat, whereas in the mouse the order is rabbit > guinea pig or human > bovine serum. The γ-globulin fraction is at least as effective as whole serum and can account for the whole of the interference, whereas the albumin fraction has no effect. However, to inhibit transmission of immunity, the γ-globulin, whether in serum or separated, must be in considerable excess relative to the antibody globulin. Fraction III of papain hydrolysed rabbit γ-globulin is several times as effective as whole rabbit γ-globulin in interfering with the transmission of antibodies in mice, whereas fractions I and II are ineffective[25]. Interference has not been observed in the transmission of antibodies across the fœtal membranes in rabbits and no information is available concerning other species.

Thus, the phenomenon of interference has been observed both with passive anaphylactic sensitization in the guinea pig and with passive transmission of immunity in the rat and the mouse. The sera of certain species interfere, whereas those of others do not, both in anaphylaxis and in transmission. In both processes the whole effect is due to the γ-globulin fraction of the serum, and fraction III of papain hydrolysed rabbit γ-globulin is considerably more effective than the whole γ-globulin, whereas fraction I is without effect. The interfering γ-globulin must be in substantial excess over the immune γ-globulin for interference to approach completion in either process. Both in anaphylaxis and in transmission interference has been attributed to competition for specific receptors on, or in, the cells.

The resemblances mentioned strongly support the assumption of an essentially similar mechanism of cellular attachment in both sensitization and transmission. There are, however, important differences between the two processes. Perhaps the most obvious is that, whereas it is the mast cells which are involved in sensitization, it is the endoderm cells of either the fœtal yolk-sac or of the fœtal or neonatal gut which mediate transmission in rabbits and rodents, although the syncitiotrophoblast may be concerned in primates[26]. Secondly, whereas sensitization only involves the assumption of attachment to receptors on the external surfaces of the cells, transmission requires transport across the cells from one pole to the other and, hence, the assumption of internal receptors. All the available evidence, both physiological[27] and electronmicrographic[28,29], indicates that in the transmission of immunity the uptake of the γ-globulin by the cells is pinocytotic and, consequently, not selective. This suggests that the receptors are probably in the walls of the pinocytotic vesicles, although they may be carried from the external surface into the vesicles when they are formed. The excess protein in solution, absorbed pinocytotically and not transmitted, is certainly degraded so that absorption and transmission are not commensurate[27].

Finally, whereas sensitization does not necessarily require a mechanism of release of the γ-globulin from the receptors, once attached, such a mechanism is implicit in the transmission of immunity.

Some of these differences between the two processes may be more apparent than real and careful comparison should result in further insight into both. It is tempting to speculate whether the observation[3] that the absorption of antibody by tissues in passive sensitization *in vivo* or *in vitro* is not commensurate with the capacity to sensitize might not be explained by pinocytosis, as in transmission. that the reversal of established sensitization by non-immune γ-globulin[30] might not depend on a mechanism of release from the receptors and subsequent competition between the free antibody and non-immune γ-globulin for the unoccupied receptors, and that the increase with lapse of time in the difficulty of reversing passive sensitization[22] might be due to the movement of the occupied receptors into the more inaccessible internal regions of the cells. Such rash speculations are warrantable at present only in so far as they may serve to indicate the lines along which further research might prove fruitful.

VIRUS ISOLATION IN THE ZONAL ULTRACENTRIFUGE

By Dr. NORMAN G. ANDERSON

Biology Division, Oak Ridge National Laboratory,* Oak Ridge, Tennessee

ZONAL centrifugation has been widely used for virus purification using either rate or equilibrium methods[1]. A limiting factor has been the small capacity of the swinging-bucket rotors generally used. Using a recently developed ultracentrifuge[2,3], I have purified large quantities of virus particles with both methods. This work is described in the present article and also a new technique which combines continuous-flow concentration with equilibrium centrifugation in cæsium chloride, followed by rate-zonal centrifugation in a sucrose gradient. The integrated method is applicable to large-scale virus isolation for research purposes or for vaccine production.

The general principles of the zonal ultracentrifuge have been previously presented[2,3]. The central problems in its development were the elimination of swinging buckets or centrifuge tubes of any sort, provision for sedimentation to occur in sector-shaped compartments, development of rapid methods for establishing and recovering large

density gradients during rotation, and perfection of means for introducing the sample zone as a very thin layer at the top or (in instances where the particles of interest float up in the density gradient) at the lower, or denser, end of the gradient. For high-speed operation, vacuum chamber enclosure and high-speed seals for pumping fluid into and out of the spinning rotor are required. Fluid line connexions are to the rotor edge and to the centre core.

Centrifuge Operation

The rotor is loaded and unloaded while spinning. At an initial speed of 3,000 r.p.m. a sucrose density gradient starting with 10 per cent sucrose is pumped to the rotor edge. Centrifugal force stabilizes the fluid against the rotor wall and prevents mixing in the density gradient. As a stream of sucrose of continuously increasing density is pumped in peripherally, the light end of the gradient is displaced toward the centre core. When the complete gradient (1,200 ml. extending, in most viral work, linearly with radius from 10 to 30 per cent sucrose) is in the rotor, additional 55 per cent sucrose is pumped to the rotor edge to fill completely the 1,625 ml. internal rotor volume, and also to begin displacing a portion of the light end of the gradient out through the central core. At this time the direction of fluid-flow is reversed, and the sample is pumped in through the core, where it is displaced out free of the core by an overlay of additional fluid having a density less than that of the sample layer. Data on the thickness of the sample layer in the rotor has been presented previously[3]. When filling is complete, the rotor is brought up to operating speed to effect the desired separations, and then decelerated to 5,000 r.p.m. for unloading. The gradient is recovered by pumping 55 per cent sucrose to the rotor edge, thereby displacing the gradient toward the rotor core, where it is funnelled into the core exit line.

The gradient is thus recovered as a stream, with the light, overlying fluid recovered first, followed by the sample zone, and then the zones of successively more rapidly sedimenting particles. For most purposes the stream is monitored by recording absorbancy in the ultra-violet range using a quartz cell with a light path of 0·2 cm (ref. 4). All work was done in zonal rotor *B*-II, the configuration and dimensions of which have been previously reported[3].

Virus Purification

In initial studies[3], formaldehyde-treated types I, II and III poliovirus were purified from tissue culture supernatant concentrates. Most of the mass in the starting zone proved to be soluble material which did not sediment under the conditions used. A single virus peak was observed in each instance, which, when reconcentrated and observed in the analytical ultracentrifuge, gave only one peak having the expected sedimentation coefficient. With crude extracts containing brome mosaic virus, a single virus peak was also observed, while a very skewed peak was seen with crude extracts containing tobacco-mosaic virus.

For more extensive investigations, *T*3 *coli* phage from cells grown on a synthetic medium were used. As a test material, 20 l. of phage-infected *Escherichia coli* culture was pumped through the rotor at 20,000 r.p.m. and a flow rate of approximately 100 ml. per min. The sedimented material was scraped off the rotor wall and resuspended in buffer at *p*H 7·5. A small amount of this lysate concentrate was placed in 20 ml. of buffer and used as the sample layer in the run shown in Fig. 1. The sample contained some soluble material, phage particles, and lysed cells. An 'ovent-marking' pen along the lower edge of the chart registered each 40-ml. fraction as it was collected. The sedimentation coefficients were calculated using a modification of the equation suggested by Martin and Ames[5]. The sedimentation coefficient for the virus peak agrees very well with the value of 476 *S* reported by Swaby[6]. When examined by phase contrast microscopy,

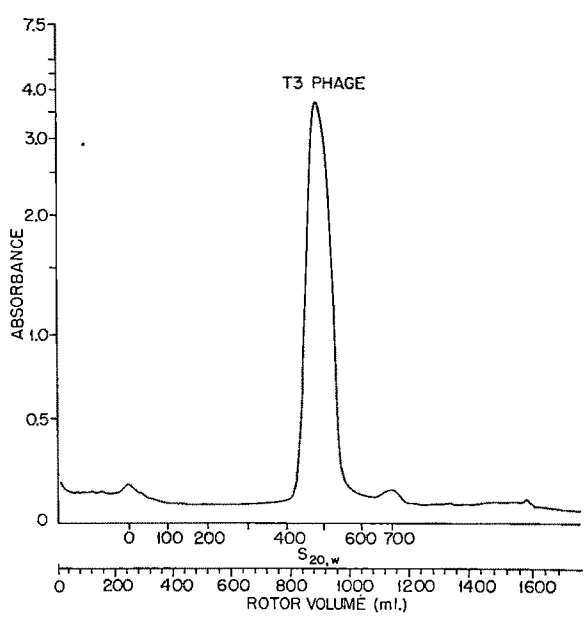

Fig. 3. Rate zonal sedimentation of *T*3 phage from phage peak shown in Fig. 2 in sucrose gradient centrifuged 2 h at 20,000 r.p.m.

the peak on the far right was found to contain lysed cell fragments. This run indicates the resolution which may be obtained with the present zonal ultracentrifuge prototype. Similar experiments were done with *T2* phage, where the separation was followed by infectivity assays.

Rotor *B*-II is not ideally suited to continuous flow work since flow through the rotor in the absence of a density gradient is not distributed evenly over the inner surface of the rotor. The following exploratory experiment was done, however, to see whether a combination of continuous flow and equilibrium-zonal centrifugation was feasible.

Fifteen litres of a low titre *T3* phage lysate was pumped through the rotor approximately 2 l./h with the rotor spinning at 20,000 r.p.m. at 5° C. The rotor was then decelerated to 5,000 r.p.m. and 100 ml. each of 1 : 3, 1 : 1 and 3 : 1 dilutions of a stock cæsium chloride solution (130 g in 70 ml. water) pumped to the rotor edge in that order. This was followed by 250 ml. of the stock cæsium chloride solution. These solutions form very thin layers at the rotor edge and rapidly diffuse to form a continuous density gradient.

After 2 h at 20,000 r.p.m. and 3 h at 5,000 r.p.m., the gradient was recovered by pumping saturated cæsium chloride to the rotor edge. The ultra-violet absorbancy of the effluent rotor stream was recorded and is shown in Fig. 2. Samples from the three peaks were examined by phase-contrast microscopy. The first peak contained lysed bacterial cells and debris, and the second only whole cells. The third peak, which banded at a density of 1·5, which is the density of *T3* phage[6], was optically empty. The ragged recording of the first peak is due to the presence of large clumps of material in the effluent stream.

The material in the third peak was diluted to decrease the density of the solvent and the virus was recovered by centrifuging at 150,000*g*. The pellet was suspended in 0·1 ionic strength Miller–Golder[7] buffer at *p*H 7·5 and rerun in the zonal ultra-centrifuge with the same gradient used for the separation shown in Fig. 1, but with a centrifuge time of 2 h at 20,000 r.p.m. The results, shown in Fig. 3, demonstrate that excellent purification of virus particles may be obtained using the combined continuous flow-density gradient method.

Rotors are now being designed which will allow a cæsium chloride gradient to be stabilized at the rotor wall while the dilute virus suspension is flowing through the rotor. The virus particles would then sediment into the density gradient rather than to the rotor wall and afterwards back into the cæsium chloride gradient. Better continuous-flow operation is also obtained by introducing the solution to be concentrated as a gradient of very gradually increasing density, or by slowly lowering the temperature of the rotor and the feed solution. In both instances, the solution is oriented against the rotor wall as it flows in, allowing efficient sedimentation to occur.

These experiments demonstrate the feasibility of zonal rotors for the large-scale purification of virus particles by rate-zonal and isopycnic zonal centrifugation, and in addition show that the latter may be combined with continuous-flow centrifugation for the concentration of virus from large volumes of solution.

Adventitious viruses have recently been discovered in vaccines previously considered safe for human use[8,9]. Since only those contaminating viruses for which specific tests are available can be detected, it is considered important to develop methods of large-scale virus purification which would decrease by several orders of magnitude the concentration of particles and viruses differing in sedimentation rate or density from the virus desired.

Where the viral nucleic acid may be removed by chemical treatment[10] or where a fraction of the naturally formed particles are devoid of nucleic acid, the possibility of isolating such hollow-headed or 'top-component' particles for the preparation of non-infective vaccines can now be considered. This approach is especially attractive where chemical inactivation of the virus results in extensive losses in antigenicity.

In most tissues, relatively few particles occur that have the sedimentation characteristics of virus particles. (Exceptions exist, as, for example, the hoof-and-mouth disease virus which has nearly the same sedimentation coefficient as a major class of ribosomes.) In the zonal ultracentrifuge, tissue breis yield a spectrum of separated particles. Fractions suspected of containing virus particles may be concentrated to small pellets for examination in the electron microscope or for infectivity assays. If the sedimentation coefficient of the virus is known, its position in the gradient may be easily calculated.

Poliovirus was provided by Dr. Jonas Salk, TMV by Dr. C. A. Knight, TMV and BMV-infected plant tissues by Dr. Myron Brakke, *T2* phage by Dr. Elliot Volkin, and *T3* phage by Dr. J. B. Bateman. I thank Dr. R. J. Huebner for advice and encouragement. This work was performed under the Joint National Institutes of Health–Atomic Energy Commission Zonal Centrifuge Program.

PURIFICATION OF RADIOACTIVE FOOT-AND-MOUTH DISEASE VIRUS

By Dr. F. BROWN and B. CARTWRIGHT
Research Institute (Animal Virus Diseases), Pirbright, Surrey

BEFORE the detailed investigation of the chemical composition and structure of a virus can be attempted it is necessary that it should be available in a pure state. Furthermore, the availability of radioactively labelled pure virus greatly facilitates biochemical studies of the early stages of virus multiplication. Preliminary investigations on the purification of small quantities of radioactively labelled foot-and-mouth disease (FMD) virus for these purposes are described in this article.

Monolayers of baby hamster kidney cells (*BHK* 21, Clone 13, ref. 1) grown in Roux flasks and containing about 10^8 cells were infected with 10^9 plaque-forming units of FMD virus of type *O* (strain 1) which had been passaged 5 times in cultured *BHK* 21 cells. After 15-min incubation at 37° the cell sheets were washed carefully three times with a medium deficient in phosphate (Hanks's saline with 0·001 M *tris* replacing the phosphate) and then incubated at 37° in 40 ml. of the same medium containing 50 μc. carrier-free, phosphorus-32-labelled phosphate. Because of the lability of FMD virus in environments at less than *p*H 7, care was taken to keep the *p*H of the medium greater than this value by periodic addition of

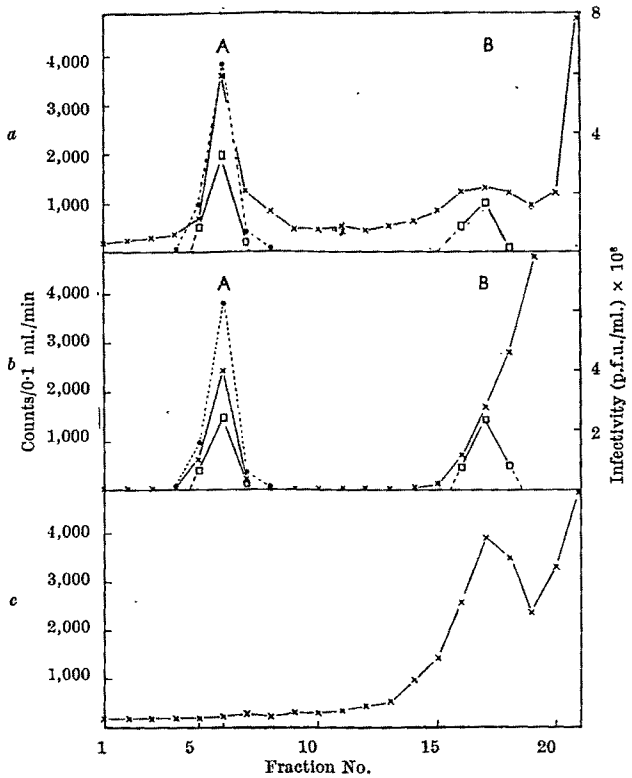

Fig. 1. Sucrose density gradient centrifugation (*S.W.* 39, 15–45 per cent sucrose, 35,000 r.p.m., 90 min) of phosphorus-32-labelled virus pellets mixed with phosphate (*a*), or deoxycholate (*b*), and of normal uninfected phosphorus-32-labelled cell extract (*c*). ×—×, Phosphorus-32; ●—●, plaque-forming units; □—□, complement-fixing activity

dilute sodium hydroxide. After 12-h incubation the medium was separated from the cells and cell debris by centrifugation at 2,000 r.p.m., cooled to 2° and mixed with an equal volume of cold saturated ammonium sulphate at *p*H 7·6 in 0·04 M phosphate buffer. All the infectivity and complement-fixing activity of FMD virus suspensions were precipitated by this procedure[2]. The precipitate was collected by centrifugation at 2,000 r.p.m. and re-suspended in 0·04 M phosphate, *p*H 7·6. Insoluble material was removed by centrifugation at 10,000 r.p.m. for 15 min in the *L* 40 head of the Spinco ultracentrifuge and the virus then deposited from the supernatant by centrifugation at 35,000 r.p.m. for 60 min. The pellet was dispersed in 0·04 M phosphate by vigorous pipetting followed by gentle agitation overnight at 2°. The recovery of virus infectivity and complement-fixing activity in these procedures is shown in Table 1.

Table 1. Concentration of Foot-and-Mouth Disease Virus (Type *O*) by Ammonium Sulphate Precipitation and Ultracentrifugation

	Volume (ml.)	Virus titre in mice (log ID_{50}/ml.)*	Complement-fixing activity (ml. 1/30 *C'* fixed by 1 ml. fraction)	Total Complement fixing activity
Initial virus	1,000	6·8	2·5	2,500
Ammonium sulphate precipitate	20	8·2	116·4	2,328
10,000 r.p.m. supernatant	20	8·5	116·4	2,328
35,000 r.p.m. supernatant	20	6·1	50·5	1,010
Pellet in phosphate	1	9·5	1,356	1,356
Pellet in 0·5 per cent deoxycholate	1	9·5	1,356	1,356

* Intraperitoneal inoculation of 0·03 ml. into 7-day-old mice.

Preliminary investigations with unlabelled virus showed that pellets prepared in this way contained cellular material because they fixed complement with cell antiserum prepared in rabbits. Partial fractionation of the virus and cellular protein could be obtained by chromatography on DEAE-cellulose. Sucrose density gradient centrifugation (*S.W.* 39, 15–45 per cent sucrose, 35,000 r.p.m., 90 min) of phosphorus-32-labelled virus pellets gave two main radioactive peaks, but there was a considerable background of radioactivity which was presumably due to cellular constituents (Fig. 1*a*). In experiments with uninfected cells, Dr. D. N. Planterose in this laboratory has found that the addition of sodium deoxycholate considerably reduces the rate of sedimentation of normal cell microsomes in sucrose gradients. Consequently, the effect of 0·5 per cent sodium deoxycholate on the behaviour of the virus in sucrose gradients was examined. The results in Fig. 1*b* show that the background radioactivity was almost completely eliminated. Furthermore, the amount of radioactivity found in peak *A* from an untreated pellet was reduced almost two-fold if the pellet was mixed with deoxycholate before centrifugation. As 0·5 per cent deoxycholate has no effect on the infectivity of FMD virus, the radioactive material which sedimented more slowly after deoxycholate treatment is presumably a phosphorus-containing cellular constituent. The amounts of complement-fixing activity and ultra-violet-absorbing substances (at 260 mμ) in peak *A* were also much lower, and the amounts in the later fractions correspondingly higher, when the pellet was treated with deoxycholate before centrifugation.

Uninfected cells which had been incubated in phosphorus-32-labelled medium for 12 h, lysed and the lysate concentrated in exactly the same way as virus suspensions gave the sucrose density gradient centrifugation pattern shown in Fig. 1*c*. It can be seen that there was no radioactive peak at the position corresponding to infective virus in Figs. 1*a* and 1*b*. In view of this observation, it was surprising that cellular material should be associated with peak *A* obtained from virus pellets centrifuged before treatment with deoxycholate. The loss from peak *A* of complement-fixing activity without loss of infectivity when the virus pellet was mixed with deoxycholate prior to centrifugation indicated that some of the 7 mμ viral protein sub-unit was present in peak *A* from untreated pellets. Previous experiments had shown that some of the 7-mμ sub-unit present in untreated virus collections was deposited with the 25-mμ infective component when spun for 1 h at 35,000 r.p.m. in the *L* 40 head, suggesting that the two components were combined. However, the 7-mμ component did not combine and deposit with purified 25-mμ component. These results indicate that there is present in untreated virus suspensions and pellets a complex of the 7-mμ component and cellular material, which has the same sedimentation characteristics in sucrose density gradients as the 25-mμ infective component but is disrupted by deoxycholate into smaller components which then sediment much more slowly in the sucrose gradient.

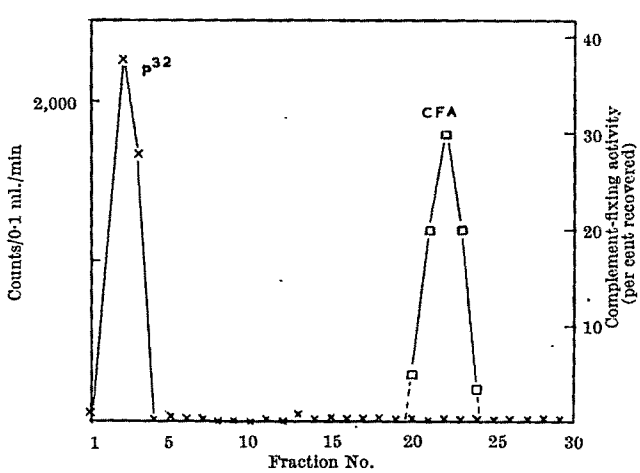

Fig. 2. Chromatography of peak *A* on 'Amberlite *IRC*-50' in 0·02 M phosphate, *p*H 6·8. Elution was carried out with increasing concentrations of phosphate. Fraction 21 was *c.* 0·2 M

The ratio of plaque-forming units and complement-fixing activity to radioactive counts in the individual fractions making up peak *A* in the sucrose gradients of deoxycholate-treated pellets (Fig. 1*b*) was remarkably constant, indicating that the material in the peak was homogeneous. A number of experiments revealed, however, that only about 5 per cent of the infectivity added to the gradient was being recovered in the fractions comprising peak *A*. These losses, which could also be demonstrated by complement-fixation tests, have been shown to be due to adsorption of virus on to the glass tubes in which the fractions were collected because recoveries of infectivity greater than 50 per cent were obtained when 10 per cent normal guinea pig serum was added to the tubes before collection of the fractions. Tubes coated with silicone also allowed good recoveries of virus.

The following experiments have been carried out to test whether peak *A* obtained by sucrose density centrifugation of deoxycholate-treated pellets is free from cellular constituents.

(1) Lowering of FMD virus suspensions to *p*H 6·8 in 0·02 M phosphate breaks down the virus into its infective RNA and 7-mμ protein sub-units[3,4]. These can then be separated by chromatography on 'Amberlite *IRC*-50', the RNA passing unadsorbed through the column, whereas the 7-mμ component is adsorbed and can afterwards be eluted with higher concentrations of phosphate[5]. Dilution of peak *A* in 0·02 M phosphate, *p*H 6·8, followed by chromatography on 'Amberlite *IRC*-50', gave the result in Fig. 2, which shows that all the radioactivity passed through the column without adsorption. The result also shows that the protein sub-unit does not contain any phosphorus. Similarly, sucrose density gradient centrifugation (*S.W.* 39, 15–45 per cent sucrose, 35,000 r.p.m., 90 min) of peak *A* after adjustment to *p*H 6·8 left the complement-fixing activity and radioactivity near the top of the tube. In contrast, this mild acid treatment did not alter the sedimentation characteristics of the radioactive constituents present in the pellets prepared from uninfected cells.

(2) Peak *A* was twice extracted with cold phenol in order to obtain the RNA. More than 80 per cent of the radioactivity was left in the aqueous RNA-containing layer. This preparation of RNA was then mixed with cellular RNA prepared by phenol extraction of unlabelled *BHK* cells and precipitated with 2 volumes of cold ethanol. After standing overnight at 0°, the precipitate was collected by centrifugation, dissolved in phosphate-buffered saline and either spun in a sucrose density gradient (*S.W.* 39, 5–20 per cent sucrose, 35,000 r.p.m., 4 h) or chromatographed on calcium phosphate[6]. In both procedures the peak of radioactivity did not coincide with any of the RNA peaks of the unlabelled cells.

(3) It is possible that unlabelled substances (for example, protein) could be present in peak *A*. However, adjustment of peak *A* to *p*H 6·8 before centrifugation in a sucrose gradient (*S.W.* 39, 15–45 per cent sucrose, 35,000 r.p.m., 90 min) did not leave any ultra-violet-absorbing substances in the position normally occupied by peak *A*. If there is a protein contaminant in peak *A* it must be broken down into smaller units at *p*H 6·8.

(4) Mixtures of the radioactive virus in peak *A* with either normal guinea pig serum or hyperimmune guinea pig serum against types *O* or *C* of the virus were centrifuged at 12,500 r.p.m. for 15 min in 2-ml. tubes in the *L* 40 head of the Spinco ultracentrifuge and the distribution of radioactivity in each tube was then measured. Some radioactivity was deposited even with normal serum or the heterotypic serum type *C*, but only the type-specific serum against type *O* caused complete precipitation of the radioactivity. Precipitation with the normal and heterotypic sera is likely to be caused by aggregation of the purified virus particles. The protein sub-unit (peak *B*, Fig. 1*b*) collected from one experiment in which radioactive virus was centrifuged was also examined in the same way. The radioactivity present in this peak was not deposited at 12,500 r.p.m. after mixing with the type-specific antiserum, thus affording more evidence that the virus sub-unit does not contain nucleoprotein.

(5) A suspension of unlabelled virus was mixed with an extract of phosphorus-32-labelled uninfected cells and concentrated with ammonium sulphate as described here. The pellet obtained by centrifuging for 1 h at 35,000 r.p.m. was then mixed with deoxycholate and centrifuged in a sucrose gradient (*S.W.* 39, 15–45 per cent sucrose, 35,000 r.p.m., 90 min). The virus peak which was obtained did not contain any radioactivity.

These experiments provide substantial evidence that the virus obtained in peak *A* of deoxycholate-treated pellets is free from substances found in uninfected cells. The possibility remains, however, that the virus peak contains non-viral substances which are found only in virus-infected cells. The methods described here are being applied to the purification of larger quantities of the virus and also to other immunological types of the virus grown in different cell systems.

HISTONES AND GENE FUNCTION

By G. C. BARR and Prof. J. A. V. BUTLER, F.R.S.

Chester Beatty Research Institute, Institute of Cancer Research: Royal Cancer Hospital, Fulham Road, London, S.W.3

SINCE the proteins principally associated with the DNA in the chromosomes of the somatic cells of mammalian and other complex organisms are histones, and since similar proteins have not been found associated with the DNA of bacteria[1], it is an attractive hypothesis that they are concerned with cell differentiation. Stedman and Stedman[2], indeed, suggested in 1951 that histones were concerned with the control of gene expression by inhibiting the functioning of genes which are not required to function in particular types of cells. Since different genes may be expected to be active in different cell types we should expect them to have different complements of histones. Although cases of tissue specificity have been reported[3], histones from a number of mammalian tissues of several species show a remarkable similarity in their starch electrophoresis patterns[4]. On the other hand, it has been found that histones from a plant source (wheat germ) are markedly different[5].

Progress has been made in the fractionation of histones by chromatography and by various extraction and precipitation procedures[6] and a number of fractions with markedly different amino-acid analyses have been obtained, for example, the fractions termed *F*1 (lysine rich); *F2a*, *F2b* (intermediate); *F*3 (arginine rich)[7]. None of these, when examined by starch-gel electrophoresis, is free from subsidiary bands, but the fact that similar fractions prepared by different methods have closely constant compositions suggests that we are not dealing with a large number of components, having compositions which merge gradually into each other, but a limited

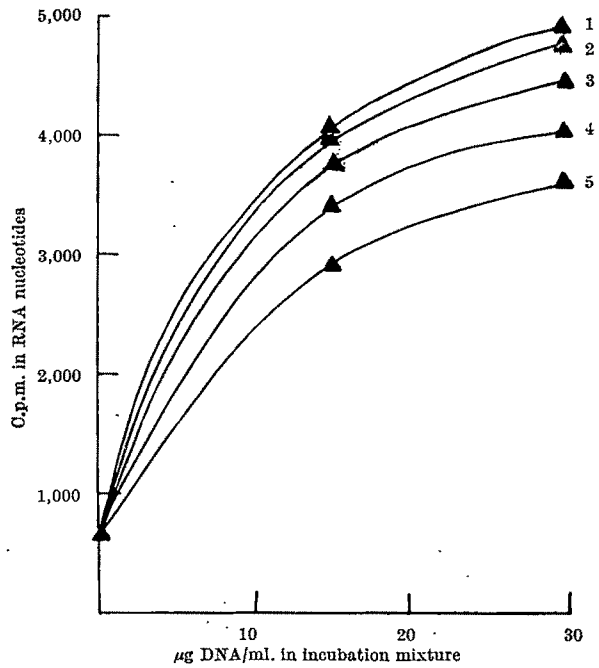

Fig. 1. RNA synthesis promoted by various DNA-histone complexes. The incubation mixture contained in 0·5 ml., 48 μmoles of *tris*-hydrochloric acid of *p*H 7·4; 4 μmoles of magnesium chloride; 2 μmoles ATP; 0·17 μmoles GTP; 0·17 μmoles CTP; 0·4 μcuries of [^{3}H]-UTP (125 μμmoles); enzyme preparation containing 92 μg of protein. Incubation for 3–15 min, 1 mg. carrier RNA added and acid insoluble alkali digest counted by liquid-scintillation

number of characteristically different proteins. If this were so we would then have to conclude that the different histones at most distinguish different classes of genes rather than individual genes. The possibility that each fraction contains a number of proteins of the same overall character, but with different amino-acid sequences, remains. This can only be settled by sequence studies which are in progress but insufficiently complete[8].

The discovery of the RNA polymerase, which uses DNA as a template[9], makes a quantitative measure of at least one aspect of gene function possible. In experiments by Huang and Bonner[10] it was found that with the native nucleohistone from pea seedlings and a polymerase from the same source, little synthesis occurred although the DNA itself was active, indicating inhibition of the process by the histone present. In reconstituted nucleohistones, prepared by adding histone to DNA in strong salt solutions, in which the complex is dissociated, and dialysing away the salt, marked inhibition of RNA synthesis occurs as compared with that in the presence of DNA, but the effects reported are variable[11].

We have attempted to obtain reproducible results in experiments of this kind, using DNA from calf thymus and histone fractions from the same source. Complexes of native calf thymus DNA and histone were formed by mixing DNA (250 μg/ml. in the final solution) and variable amounts of histone in 1 M sodium chloride and gradually dialysing away the salt against water and a suitable buffer over a period of 6 h, so that the final complex was in a medium of 0·05 M *tris* buffer at *p*H 7·4, as performed by Huang and Bonner[10]. For the most part, the complexes formed were gelatinous suspensions and were added to the incubation mixture as such. We found it impossible with these materials to obtain soluble complexes of the type described by Huang and Bonner[10]. Reducing the final concentration of the buffer to 0·01 M *tris* did not bring the complex into solution. The RNA polymerase used was purified from *B. megaterium* as described by Barr and Butler[12] and had an absolute requirement for DNA; RNA was inactive as primer.

Table 1 indicates the ability of the DNA to promote synthesis and the complete inability of the native nucleohistone in this respect. Boiling the nucleohistone solution for 5 min which denatures the DNA and may be expected to disturb any specific histone–DNA interaction, and possibly solubilize part of the histone, restores the ability to some extent.

Table 1. Priming Ability of Native Nucleohistone and DNA from Calf Thymus

Each incubation mixture contained 30 μg DNA and 101 μg of the enzyme protein

Primer used	C.p.m. in RNA
Calf thymus DNA	1,840
Calf thymus nucleoprotein	150
Boiled calf thymus nucleoprotein	530
Control (no primer)	120

Fig. 1 shows the ability of various complexes of DNA and histone to promote RNA synthesis. The 1 : 1 complex was 75 per cent as active as DNA, but some of this loss of activity may be due to the presence of traces of ribonucleases in the histone. Fig. 2 demonstrates the ability of complexes of DNA with different calf thymus histone fractions to promote RNA synthesis. The effects of the fractions are much larger and could not possibly be attributed to any ribonuclease contamination of the histones.

Complexes of calf thymus DNA and poly-*l*-lysine were also prepared and investigated in the same way. Table 2 shows that all complexes containing a ratio of poly-*l*-lysine to DNA of 0·5 or more (w/w) were completely inactive as primers.

It is evident from these results that the histone fractions produce much greater effects when present in excess of the natural amount than would be expected if they caused specific inhibitions of RNA synthesis on portions of the DNA molecules. *F2a*, *F2b* and *F3* comprise approximately 35, 25 and 20 per cent, respectively, of the

●, DNA; ▲, *F*1–DNA complex; □, *F2a*–DNA complex; ○, *F2b*–DNA complex; △, *F*3–DNA complex. The enzyme preparation contained 101 μg protein in each case

Table 2. Polylysine–DNA Complexes as Primers for RNA Synthesis

Wt. ratio Polylysine : DNA	Counts incorp./mols RNA	Inhibition (per cent)
0	3,790	
0·25	2,990	24
0·5	950	84
1·0	590	94
1·3	400	100
Control (no primer)	400	

All mixtures contain 40 μg DNA present in the various complexes. Incubation was carried out with 80 μg of enzyme-protein.

whole histone, but each causes more than 80 per cent inhibition of RNA synthesis if the complex containing 15 μg of DNA is used and 55 per cent inhibition with 30 μg DNA, while *F*1, which is about 20 per cent of the whole histone, causes total inhibition of RNA synthesis at all concentrations used. It follows that *F*1 inhibits RNA synthesis in all RNA molecules and not merely those with which it had a special relationship in the native nucleohistone. Moreover, the artificial peptide poly-*l*-lysine is an extremely effective inhibitor.

It clearly follows that the inhibition of RNA synthesis in reconstituted nucleohistone is unspecific. However, there is no evidence in our experiments that reconstitution of the original native material can be achieved by the methods used. The results obtained could be due to inability to prepare reconstituted nucleohistones in a suitable form. Nevertheless, reconstitutions from the whole histone are surprisingly active, and this suggests that the physical state of the material is not of prime importance. Whether there is any correspondence between the sequence of bases in DNA and the sequence of amino-acids in histone must remain an open question until further fractionations and sequence investigations have been carried out. But it may be observed that even if such a correspondence were shown to exist, some other mechanism would have to be postulated to ensure the presence and removal of particular histone molecules at the appropriate times. This is easier to envisage with a limited number of histone types as there could be proteolytic enzymes or endopeptidases which act specifically on one type, especially as it has been shown[13] that different histones have characteristic *N*-terminal groups.

We are indebted to Mr. E. W. Johns for providing the histone and histone fractions used. This investigation was supported by grants to this Institute from the Medical Research Council, the British Empire Cancer Campaign, the Anna Fuller Fund, and the National Cancer Institute of the National Institutes of Health, U.S. Public Health Service. We thank the Fellowship Committee of the Royal Marsden Hospital for the award of a studentship to one of us.

POLYURIDYLIC ACID AND AMINOACYL TRANSFER TO MAMMALIAN RIBOSOMES

By JUNE M. FESSENDEN* and Prof. KIVIE MOLDAVE

Department of Biochemistry, Tufts University School of Medicine, Boston, Mass.

STIMULATION of amino-acid incorporation by synthetic polynucleotides in cell-free systems from *E. coli*[1–6] and mammalian tissues[7–12] has been reported. Previous investigations in this laboratory[12] demonstrated that aminoacyl transfer from *s*RNA to rat liver ribosomes was stimulated by the addition of several synthetic polynucleotides. This stimulation was greater when ribosomes were pre-incubated with crude soluble enzyme preparations that catalysed aminoacyl transfer. It was suggested that, on pre-incubation, a component of ribosomes, possibly messenger RNA, was removed by a factor present in crude soluble enzyme preparations; the stimulation on addition of polynucleotides to pre-incubated ribosomes suggested that endogenous messenger RNA was replaced by synthetic polynucleotides. Evidence presented here suggests that: (*a*) loss of endogenous messenger RNA activity and its replacement by polynucleotides are time-dependent processes; (*b*) the activity responsible for the loss of endogenous messenger RNA activity is different from the enzymes which catalyse aminoacyl transfer; (*c*) synthetic polynucleotide-enhanced incorporation represents the formation of amino-acid homopolymers.

Incorporation of amino-acids from aminoacyl *s*RNA into rat liver ribosomal protein is catalysed by the soluble portion of cells and requires guanosine triphosphate and glutathione. Most of the transferring activity in the non-particulate fraction of rat liver homogenates remains soluble after precipitation of the 'amino-acid-activating enzymes' fraction at *p*H 5 (*p*H 5 supernatant). Two protein fractions (aminoacyl transferases (or polymerases) I and II) have been resolved and partially purified in this laboratory, which are inactive individually but when combined catalyse aminoacyl transfer in presence of GTP and glutathione[13–16].

Incubation of ribosomes with polyuridylic acid (poly U) and *p*H 5 supernatant led to a two- to four-fold stimulation of phenylalanine incorporation from ^{14}C-phenylalanyl *s*RNA (Fig. 1, zero time values). Pre-incubation of ribosomes at 37° with *p*H 5 supernatant, GTP and glutathione, prior to addition of the labelled substrate ^{14}C-phenylalanyl *s*RNA, led to a decrease in the ability to incorporate amino-acid; most of the decrease in ribosomal activity occurred within the first few minutes of pre-incubation (Fig. 1). Addition of poly U to pre-incubated ribosomes led to a marked stimulation of aminoacyl transfer, particularly after the first few minutes of pre-incubation. These results are consistent with the time-dependent breakdown or release of endogenous ribosomal components which are then replaced by polynucleotides.

In contrast to experiments with *p*H 5 supernatant, addition of poly U to incubations with purified transferases I and II did not lead to a marked increase in phenylalanyl transfer. Further, ribosomes pre-incubated with transferases I and II did not exhibit a loss of activity as in experiments with *p*H 5 supernatant[12]. Experiments with ribosomes pre-incubated with *p*H 5 supernatant (Fig. 2*A*) indicated that incorporation was essentially completed after 4 min of incubation with ^{14}C phenylalanyl *s*RNA. Addition of poly U markedly stimulated phenylalanyl transfer as compared with the results with polycytidylic

* Present address: Public Health Research Institute of the City of New York, N.Y.

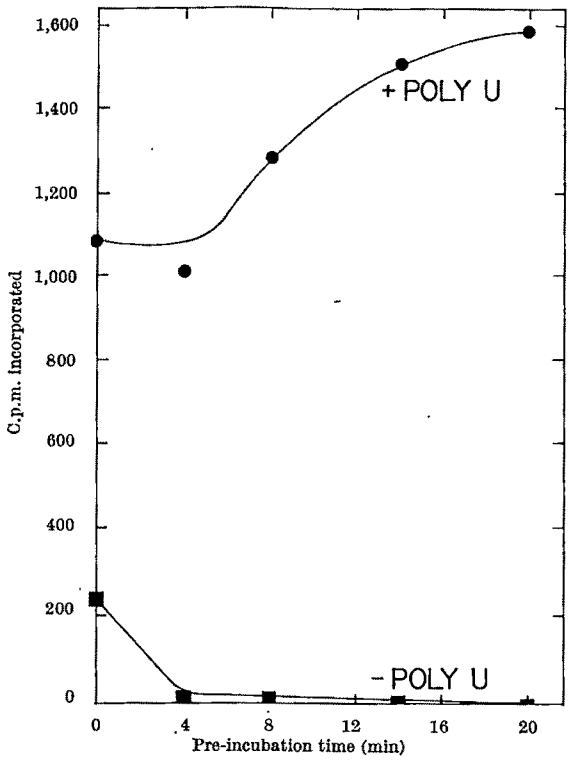

Fig. 1. Effect of pre-incubation time and polyuridylic acid on aminoacyl transfer. Approximately 0·7 mg of ribosomes was incubated at 37° for varying periods of time in the presence of 1 μmole of GTP·$MgCl_2$, 10 μmoles of glutathione, and 10 mg of *p*H 5 supernatant protein in a total volume of 1·6 ml. After 0, 4, 8, 14 and 20 min of pre-incubation, 0·08 mg (2,500 c.p.m.) of ^{14}C-phenylalanyl *s*RNA (squares, −poly U) or ^{14}C-phenylalanyl *s*RNA plus 0·2 mg of polyuridylic acid (circles, +poly U) were added and incubation, in a final volume of 2 ml. was continued for an additional 20 min

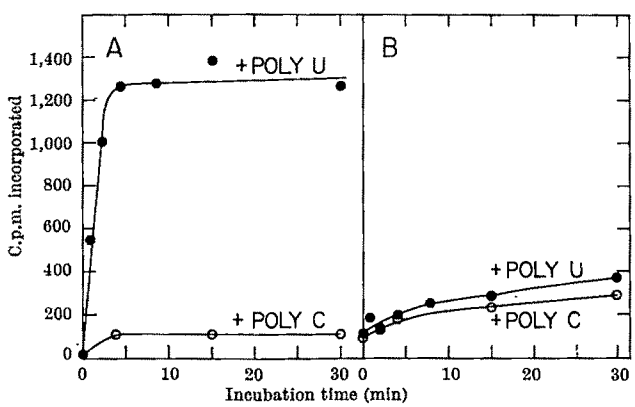

Fig. 2. Effect of polyuridylic acid on the time-dependent aminoacyl transfer to pre-incubated ribosomes. Approximately 0·7 mg of ribosomes were incubated at 37° for 8 min in the presence of GTP, glutathione and *p*H 5 supernatant (*A*) or transferases I and II (*B*) as described in Fig. 1. ^{14}C-phenylalanyl *s*RNA and 0·2 mg of polyuridylic acid (closed circles, +poly U) or 0·2 mg of polycytidylic acid (open circles, +poly C) were then added and incubated for varying periods of time as shown

acid (poly C) or in the absence of synthetic polynucleotides. Aminoacyl transfer, in experiments with ribosomes pre-incubated with combined transferases I and II (Fig. 2*B*), was not significantly stimulated on addition of poly U or poly C. Inability of purified transferases I and II to catalyse the decrease in endogenous ribosomal activity, and the subsequent failure to exhibit a significant poly U effect, are consistent with the suggestion that an additional factor is present in the *p*H 5 supernatant, responsible for the degradation of the endogenous messenger associated with ribosomes[12].

Previous results with polynucleotides varying in base composition suggested that the polynucleotide-enhanced incorporation was specific for individual amino-acids and did not involve the simultaneous transfer of several of, or all, the *s*RNA-bound amino-acids[12]. The incorporation of ^{14}C-phenylalanine from *s*RNA containing a complement of endogenous unlabelled amino-acids, in absence of poly U, probably reflects synthesis of amino-acid heteropolymers. The difference in aminoacyl transfer in presence and absence of poly U might reflect synthesis of polyphenylalanine while endogenous incorporation, in absence of poly U, probably reflects synthesis of protein. The effect of poly U was examined with ^{14}C-phenylalanine-labelled *s*RNA preparations in the presence (^{14}C-phenylalanyl *s*RNA-'*A*') or absence (^{14}C-phenylalanyl *s*RNA-'*B*') of other *s*RNA-bound ^{12}C-amino-acids. When ^{14}C-phenylalanyl *s*RNA-'*B*' was added to pre-incubated ribosomes, in absence of poly U, little incorporation occurred (Fig. 3); significant incorporation was observed with ^{14}C-phenylalanyl *s*RNA-'*A*' under similar conditions. These results are consistent with the obligatory incorporation of all amino-acids in the course of protein synthesis[17]. Addition of poly U markedly stimulated ^{14}C-phenylalanyl transfer from ^{14}C-phenylalanyl *s*RNA-'*A*' and ^{14}C-phenylalanyl *s*RNA-'*B*' preparations. Estimates on the basis of carbon-14 incorporated indicate that the poly U-stimulated incorporation of radiocarbon from both preparations is of the same order of magnitude. These results are consistent with the poly U-enhanced formation of polyphenylalanine in this system, and suggest that, in contrast to the endogenous activity exhibited by ribosomes, synthetic polynucleotide-stimulated aminoacyl transfer is specific and does not involve other amino-acids. Polyuridylic acid-enhanced incorporation of phenylalanine thus appears to reflect formation of amino-acid homopolymer while endogenous incorporation may represent formation of amino-acid heteropolymers.

This work was supported in part by the American Cancer Society (research grant *P*-177) and the U.S. Public Health Service (research grant *AM*–01397, and Research Career Program award *K*3–*GM*–4124). We acknowledge the

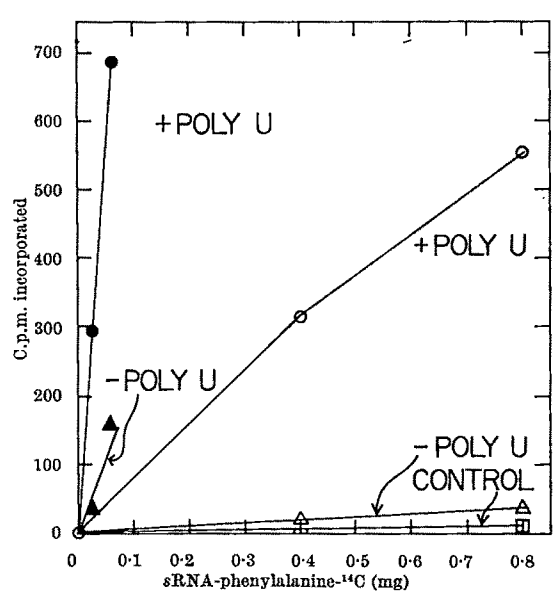

Fig. 3. Effect of polyuridylic acid on aminoacyl transfer from ^{14}C-phenylalanyl *s*RNA, in the presence and absence of other *s*RNA-bound amino-acids, to pre-incubated ribosomes. Approximately 8 mg of ribosomes were pre-incubated for 8 min as described in Fig. 1. Varying concentrations of aminoacyl *s*RNA labelled with ^{14}C-phenylalanine (^{14}C-phenylalanyl *s*RNA-'*A*', specific radioactivity approximately 32,000 c.p.m. per mg RNA) were added with (closed circles, +poly U) and without (closed triangles, −poly U) 0·2 mg of polyuridylic acid and incubated for 20 min. Similar incubations were carried out with *s*RNA, stripped of its endogenous amino-acids at *p*H 10 and containing only ^{14}C-phenylalanine (^{14}C-phenylalanyl *s*RNA-'*B*', specific radioactivity approximately 5,000 c.p.m. per mg RNA) in the presence (open circles, +poly U) and absence (open triangles, −poly U) of polyuridylic acid. The controls (open squares) represent incubations of ^{14}C-phenylalanyl *s*RNA-'*B*' with ribosomes in the absence of *p*H 5 supernatant

PACEMAKER HIERARCHIES CONTROLLING THE BEHAVIOUR OF HYDRAS

By Dr. L. M. PASSANO and Mrs. C. B. McCULLOUGH
Department of Biology, Yale University

A GOAL of 'behavioural physiology' is to analyse the behaviour of an organism into its functional components and then to explain their integrated activity in terms of the individual activities of sense cell, nerve cell and muscle unit. The relative simplicity of the coelenterate nervous system makes these animals exceptionally favourable material for such an approach to the study of behaviour.

Rhythmically occurring impulses, varying in frequency from 1 to more than 12 per min, can be recorded from intact and essentially undisturbed hydras of several species[1]. These regular pulses are cryptic, that is to say, they are not directly correlated with any movement of the animal, and are not dependent on external sensory stimuli. They originate from any one of a number of pacemaker loci near the base in the lower column or stalk, and are conducted without decrement throughout the column to the hypostome. We have termed these impulses 'rhythmic potentials' and their originating pacemakers and conducting network the 'rhythmic potential system'[1]. Circumstantial, but incomplete, evidence suggests that the rhythmic potential system is a network of endodermal neurones.

We shall show here that these rhythmic potential pacemakers and their conducting system are responsible for a complex behavioural sequence in hydras, co-ordinating regional pacemaker centres of the tentacles and sub-hypostome. These pacemaker systems are shown in Table 1. The picture which has emerged of the mechanism of integration in hydras has served, in turn, as the basis for a new theory of the origin of the nervous system[2].

The frequency of rhythmic potential impulses in *Hydra littoralis* Hyman can be affected by electrical, mechanical or light stimuli. The initial reaction to a light stimulus of moderate intensity is an interruption of the existing rhythm (Fig. 1, above). After a short, somewhat variable period, rhythmic potential pulses re-occur at an enhanced frequency. The extent and duration of this enhancement depends on the state of dark adaptation of the animal prior to stimulation, the strength, duration and wave-length of the light stimulus, the nutritional state of the animal, and probably to other variables as well. The

Table 1. Classes of Pacemaker Systems in Hydras

Name	Locus	Function	Conducting network
Rhythmic potential (RP)	Lower column	Co-ordinated activity of organism; control other pacemaker systems	RP system; endodermal nerve-net (?)
Contraction burst	Sub-hypostome	Periodic total contraction of column with ectodermal muscles	Ectodermal nerve-net (?)
Attachment burst	Tentacle base	Initiate contraction burst in locomotor sequence	RP system (?)
Tentacle	Proximal part of tentacle	Contract tentacles. May precede contraction burst	Unknown; not conducted in column

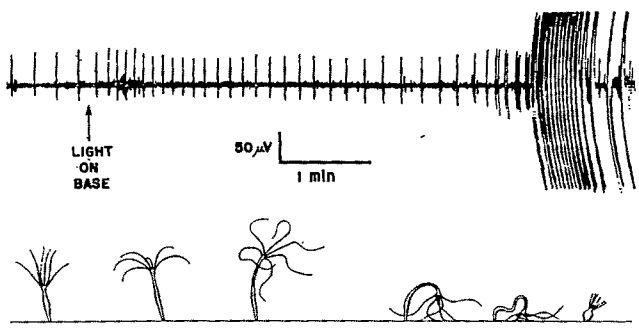

Fig. 1. Response of dark-adapted *Hydra littoralis* to localized illumination of the base. Total duration of record 7 min. Above, electrical potentials; below, behavioural response with aborted locomotion

heightened frequency usually continues for at least 3–5 min, and will last long after the stimulus is removed. Very short light flashes, such as those produced by a photographic flash-bulb, are not effective, but stimuli lasting 0·2 sec or longer regularly cause at least a transient rise in rhythmic potential frequency. Stimulation often also causes a change in the effective pacemaker with the enhanced frequency originating from a previously inactive locus[1].

Localized light stimulation of the base of the animal alone duplicates the effect of general illumination on rhythmic potential pacemakers.

The behavioural response sequence of normal *H. littoralis* to weak illumination has been investigated using time-lapse cinematography with infra-red sensitive film. When undisturbed and especially after they are put in the dark (or in light of greater than 580 mμ wave-length, 'hydra dark'), polyps usually show regular contraction bursts. Every 5–10 min they shorten into a tight ball, and then re-elongate their column and tentacles. Each shortening consists of a more or less consistent number (10–15 in *H. littoralis*) of discrete, co-ordinated contractions of the longitudinally arranged ectodermal muscles of the column. Following tentacle attachment the burst shows the maximum number of contractions[3]. Bursts can occur in a regular manner, at about 8–10 per h, or they may show a less regular pattern.

Under natural conditions, responses to light can impose a diurnal cycle of behaviour on hydras. At dawn the contraction frequency shows an abrupt rise to twice the night-time level. This frequency gradually declines during the day and then returns to the dark-level about 2 h after sunset[3]. The same response occurs on artificial illumination of the dark-adapted animal.

Each contraction of the burst is preceded by a slow, compound electrical potential which is conducted throughout the column by a separate system from that conducting the rhythmic potentials. The contraction burst potentials

(Table 1) originate in the sub-hypostomal region of the column just proximal to the tentacle insertions. Tentacle extirpation does not block contraction bursts, but decapitation of the sub-hypostome usually halts bursts completely[3,4] for an hour or more, and subsequent bursts, while normal, occur much less frequently for some hours. The localization of this pacemaker locus is confirmed by the finding that localized illumination of the sub-hypostome can interrupt an already initiated contraction burst.

The behavioural sequence following illumination of the dark-adapted, 48-h starved hydra is characteristic and quite sterotyped. For the first 5–10 sec there is no behavioural response; then a seemingly smooth elongation of the column and tentacles occurs, causing the animal to become half again as extended as is typical for the species in the dark. There then ensues a period, of variable duration, but usually lasting at least 2 min, of behaviour reminiscent of hydras initiating a feeding behaviour sequence[5]. The head and upper column sway from side to side, and the entire column may slowly swing around the attached base as in the photokinetic responses described by Haug[6]. The tentacles squirm and usually show co-ordinated lifting movements towards the central vertical axis. Sometimes the latter occur with asymmetrical contractions of the column just below the sub-hypostome, giving a combined nodding-tentacle sweeping movement that is very characteristic. Time-lapse motion pictures of this phase give the appearance of searching movements. Then tentacle activity increases and they tend to spread out on the substratum or surface film and attach to it, whereon a vigorous lengthy contraction burst occurs. Often the animal succeeds in wrenching its base loose from its attachment, initiating a locomotor step.

If the illumination is directional, the responses prior to the contraction burst often lead to the extension of the animal and tentacle attachment in the direction of the light source. The induced locomotion is then in the direction of the light. If the polyp attaches to the surface film, it will float away from its previous position. Tentacle attachment is much less characteristic of recently fed animals, so that they do not show so strong a locomotor component to their light response.

The increase in rhythmic potential frequency that follows light stimulation, and the specific and recognizable behavioural sequence after illumination of the dark-adapted hydra, together suggest a causal relationship between rhythmic potential frequency and co-ordinated activity of tentacles and columnar muscles. This hypothesis can be tested experimentally, since rhythmic potential frequency is increased by localized illumination of the base of the polyp, while leaving the major part of the column and the entire hypostome and tentacles in darkness.

The electrical activity of individual dark-adapted *H. littoralis* was recorded in the manner previously described[1], while they were observed under red light (590–1,000 mμ wave-length). The light stimulus was a 0·5-mm diameter spot of white light delivered through a polished acrylic plastic cone opaqued to the tip. Stimulation was continued until the contraction burst commenced, although the response, once initiated, will continue to completion without continuous stimulation.

The results were unequivocal: localized light stimulation of the edge of the base causes an abrupt increase in rhythmic potential frequency coincident with the illumination behavioural sequence, culminating in a contraction burst. A typical trial is shown in Fig. 1. Elongation was discernible within a few seconds of the increase in rhythmic potential frequency. Bending of the column, nodding and co-ordinated tentacle lifting all occurred. When tentacle attachment occurred, it was always accompanied by a rapid burst of 'attachment burst'[1] (Table 1) impulses. A vigorous contraction burst then ensued.

In a single trial, where localized light stimulation failed to cause an increase in rhythmic potential frequency, there was no evidence whatsoever of the behavioural response. Similarly, localized hypostomal light stimulation neither affected rhythmic potential frequency nor led to the behavioural light response. Rather, it inhibited the contraction burst pacemaker.

As a result of these findings we are able to interpret certain behaviour patterns of hydras in physiological terms. At the conclusion of the spontaneous contraction burst, the discharge rate of the rhythmic potential pacemaker loci is reset, probably as a result of the mechanical stimulation caused by the shortening of the column. This enhanced frequency gradually declines again to a 'basal' level, while the contraction burst pacemaker recovers. Eventually the latter escapes rhythmic potential inhibition, another contraction burst occurs, and the cycle is repeated. The interaction of these two centres—the rhythmic potential pacemaker showing frequency changes in the shape of a saw-toothed curve, the longer segments of which have a negative slope, and the contraction burst centre showing a curve the mirror-image of the former curve and representing potential activity—generate the spontaneous activity pattern which was first described by Trembley[7]. Such interacting systems fit the theoretical model of endogenous pacemakers suggested by Bethe[8]; they may also provide an example of the central pacemaker the spontaneous rhythm of which is frequency modulated by feed-back from an effector[9].

The 'activity potential' of the contraction burst pacemakers seems to be a physiological example of psychological 'energy'. Repeated interruption of spontaneous contraction bursts by localized hypostomal illumination becomes progressively less effective until inhibition finally fails entirely. A model system consisting of a single light-sensitive neurone with one or more pacemaker loci could account for this result.

These findings show that the rhythmic potential system controls quite complex behavioural sequences in hydras, and support the view that there are several pacemaker systems in these animals, arranged hierarchically, which together act as the central nervous system. Pacemakers and their conducting systems provide the integrating mechanism responsible for the co-ordinated behaviour of these animals. Their morphological basis remains obscure, but from their properties it seems likely that neurones are involved. But these pacemakers are not hypothetical; four different pacemaker systems have been differentiated and localized (Table 1) and more may well occur. We believe that the rhythmic potential pacemaker system is responsible for the endogenous rhythmic activity of hydras and that this system dominates the other pacemakers. However, complex behavioural sequences can occur independent of the rhythmic potential system, and sensory stimuli such as light or mechanical deformation can act directly on 'subordinate' centres. The lack of complete physiological dominance of the rhythmic potential pacemaker system emphasizes the diffuse nature of the coelenterate nerve-net. Such diffuse pacemaker activity is a primitive and fundamental property of the nervous system. It precedes, phylogenetically, the appearance of ganglionic centres[2], yet it may well persist within the central nervous systems of members of more advanced phyla.

RADIOPHYSICS

Neutral Hydrogen in the Virgo Cluster

Neutral hydrogen has recently been detected in absorption in the Virgo cluster of galaxies by measurements of the spectrum of the radio source Virgo *A* (*M*87). The observations were made using the Australian 210-ft. radio telescope and a parametric frequency-switching receiver[1].

Attempts to detect 21-cm emission from clusters of galaxies have so far proved unsuccessful[2]. On the other hand, absorption measurements on bright radio sources should be capable of detecting lower concentrations of hydrogen. However, measurements at Jodrell Bank[3] have shown that the opacity of any neutral hydrogen in front of Virgo *A* is less than 2 per cent. To measure an opacity well below this limit required a frequency-switching receiver with a low noise temperature (170° K), and a careful calibration of all unbalance effects in the receiver. The effect of any difference in the overall gain of the system between the two frequencies being compared was eliminated by determining the spectrum of Virgo *A* relative to that of the Moon. Frequency separations of up to 3 Mc/s were used, the frequencies being displaced successively to cover the frequency range 1,418 Mc/s–1,406 Mc/s (equivalent to radial velocities of +500–+2,900 km/s). The receiver bandwidth was 1·5 Mc/s.

Fig. 1*a* shows the spectrum of Virgo *A* constructed from the differential measurements, assuming that the comparison source, the Moon, is a black body. The differences measured for each frequency pair have been referred to the point at a red shift of 1,700 km/s. The errors shown are the standard deviations of each night's measurements for a given pair of frequencies. Because we have constructed the spectrum from the differences, the errors accumulate at each end of the velocity range. The expected spectral slope for a spectral index[4] of 0·83 has been drawn as a broken line in Fig. 1.

As a control experiment, a similar series of observations were made on the radio source 3*C*353, identified with a 13th magnitude galaxy in a region of the sky well away from the Virgo cluster. The results are plotted in Fig. 1*b*,

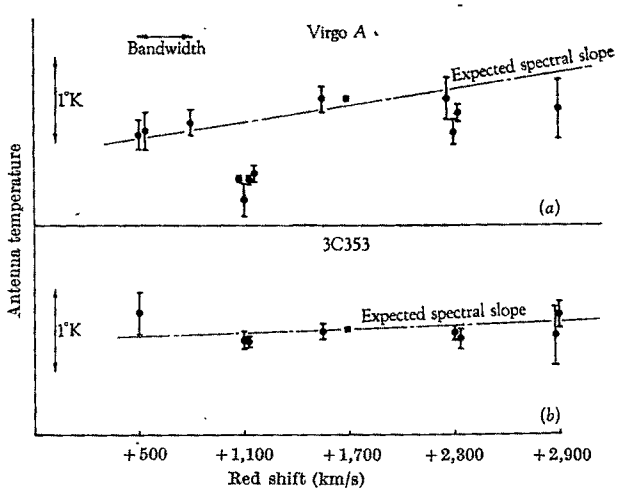

Fig. 1. Measurements of the spectra of the radio sources Virgo *A* and 3*C*353 relative to that of the Moon at wave-lengths near 21 cm. The change in antenna temperature for a 210-ft. telescope is shown as a function of the red shift

where the broken line indicates the slope corresponding to a spectral index[4] of 0·64.

The measurements on Virgo *A* show absorption amounting to 0·65° K in antenna temperature at a red shift of 1,100 km/s, close to the recession velocity of *M*87. With an antenna temperature for the source of 125° K, the corresponding opacity is 0·5 per cent. The width of the absorption feature cannot be determined accurately because of the bandwidth used (equivalent to 300 km/s), but it is not greater than 500 km/s. If the optical depth of the gas is τ, the number of ground-state hydrogen atoms per square centimetre column in the line of sight is N, and the spin temperature is T_s °K, we have (following Wild[5]):

$$\frac{N}{T_s} = 3{\cdot}85 \times 10^{14} \int_0^\infty \tau\,(\nu)\,d\nu$$

where ν is the frequency in c/s. The absorption observed corresponds to $N/T_s \doteqdot 3 \times 10^{18}$ atoms/cm² °K, if it is assumed that the absorbing gas completely covers the radio source.

If the hydrogen could be seen in emission away from Virgo *A*, we could determine the values of N and T_s separately. Attempts were made to observe emission at a velocity of 1,100 km/s at a point displaced 1° in right ascension from Virgo *A*. The telescope was driven from this point in azimuth (minimizing ground-radiation effects) to a point well outside the cluster. No emission greater than 0·2° K was detected with the bandwidth of 1·5 Mc/s.

The absence of any significant absorption in the spectrum of 3*C*353, as well as Field's failure to detect absorption in the spectrum of Cygnus *A*[6], suggest that the neutral hydrogen observed is associated with the Virgo cluster. The red shift and the relatively narrow velocity dispersion of the absorption profile also support this interpretation. Although the distribution of the hydrogen cannot be determined from the present measurements, we can consider three possibilities: the gas might be associated with *M*87 itself, or be distributed homogeneously throughout the cluster, or be in the form of a cloud in front of Virgo *A*.

Because of the intense radiation flux in the vicinity of *M*87, any gas in that galaxy will have a high spin temperature and so a low opacity[7]. The amount of hydrogen required in *M*87 to produce the observed absorption would be well above the limit determined from emission measurements on elliptical galaxies.

If the neutral hydrogen seen in absorption is assumed instead to fill the Virgo cluster homogeneously and *M*87 is near its centre, there would be emission at 21 cm with a brightness temperature of $2\,\tau\,T_s$. The lack of observable emission thus limits T_s to less than 20° K. This is somewhat lower than the value predicted by Field[8] for intergalactic, non-cluster space. With this limit on T_s, we have $N < 6 \times 10^{19}$ atoms/cm². Using de Vaucouleurs's value of 750 kiloparsec[9] for the radius of the Virgo cluster (his "Virgo *E*") leads to a density of less than 2×10^{-5} atoms/cm³ and a total mass of gas less than 10^{12} solar masses, or about 10 per cent of the mass of the galaxies in the cluster[10].

The absorption measurements show that the velocity dispersion of the gas is less than the velocity dispersion of the member galaxies of the Virgo cluster, ±550 km/s[9]. For this reason, it may be preferable to consider the hydrogen to be concentrated in a small cloud which

happens to lie directly in front of $M87$. If the cloud does not extend as far as 1° from Virgo A, we cannot exclude a higher value of T_s, and the density of the hydrogen can be increased considerably. However, the number of such clouds must be limited since no emission has been detected from them in other parts of the cluster. An examination of possible cloud models shows that the total mass of hydrogen they would contain cannot be more than about 10^{12} solar masses.

Thus whatever the distribution of the neutral hydrogen its total mass appears to be insufficient to affect the dynamical instability of the cluster suggested by application of the virial theorem to its brighter member galaxies.

Further observations are planned, using a narrower bandwidth, to determine the width of the absorption profile more accurately.

Measurement of Radio Sources at Centimetre Wave-lengths

In future, the limit of detection of faint radio sources, at wave-longths of 10 cm and less, is likely to be set by the radiation from water vapour and rain in the troposphere[1,2]. The dominant factor is the minute-to-minute fluctuations in received power, which may be as much as 2° K at λ 3·7 cm. These fluctuations are greatly in excess of the receiver noise fluctuations, and may destroy all the benefit of using a modern low-noise amplifier such as a maser.

For a large radio telescope, the Rayleigh distance may be much greater than the height of the troposphere; when this is so, a very simple difference technique may be used to eliminate the water vapour fluctuations, but still detect the extra-terrestrial radio sources.

The power from a circular aperture of diameter D flows within a cylinder in the near zone, changing to a conical beam beyond the Rayleigh distance D^2/λ. Consider a dish fed by two feeds side by side in the focal plane, such that the far-zone beams are just separated. Then the near zone beams are cylinders inclined at an angle θ, equal to the beam width, which overlap throughout the near zone, becoming just separated at the Rayleigh distance. Let the receiver be made to switch between the two feeds and record the difference in power. Then an extra-terrestrial source drifting through the two beams will give an S-shaped record with amplitude double the normal amplitude; tropospheric sources are received by both feeds and produce little or no output.

As a numerical example, consider a 100-ft. dish operating at λ 3 cm. The Rayleigh distance is 30 km. In middle latitudes, tropospheric water vapour is mostly at heights below 2 km, that is, in the lowest 1/15 of the near zone. If the dish were uniformly graded, at least 20 : 1 rejection of water vapour radiation would be expected. When allowance is made both for the grading of the dish, and for the grading of water vapour with height, this figure should be increased, perhaps by a factor 2.

The proposed 2-feed system has already been used satisfactorily at longer wave-lengths (λ 50 and λ 22 cm) on the 250-ft. dish at Jodrell Bank (Conway, Long and Daintree, in preparation). The system gains in sensitivity, but loses with respect to confusion, over a normal single beam. Confusion is notoriously a hazard at metre wave-lengths, but the confusion limit at centimetre wave-lengths is below that set by receiver noise and is far below the limit set by water vapour.

The two-feed system is of little use for investigating sources the angular size of which greatly exceeds one beam width. But the argument given here would suggest that it may be the only method for investigating the discrete radio sources at short wave-lengths.

PHYSICS

A New Instrument for Atmospheric Ozone

Recent theories of the atmospheric circulation ascribe the well-known mid-latitude spring increase in total ozone to the release into the lower stratosphere, during the breakdown of the circumpolar westerlies, of ozone which has been carried to the winter pole by air movements and stored there[1–6]. The details of this process of accumulation remain speculative, however, until many more ozone observations in the polar night become available on a routine basis. The internationally accepted standard ozone instrument, the Dobson spectrophotometer, normally uses sunlight; useful results can be obtained on the full moon[7,8], but this demands an increase in observing skill as well as imposing a serious limitation on continuity.

The idea of using stars for this purpose is by no means new[9–11], but the photographic methods which have been used require for good results an elaborate and expensive telescope. We have found it possible to construct a relatively small and inexpensive instrument with which we hope to carry out a series of observations at Resolute (lat. 74° 43′ N.) during the winter of 1963–64. As in the Dobson instrument, two wave-bands A and B in the ultra-violet, of which A is more strongly absorbed by ozone than B, are isolated by a monochromator and their relative intensities are measured. The derivation of the ozone amount, including the use of the 'long' and 'short' methods, follows exactly the procedure developed by Dobson and his associates[12]. Our method of measuring the intensities, however, is different. The two wave-bands fall on separate photomultipliers (E.M.I. type 6056) and the intensities are measured by the pulse-counting technique[13]. The telescope has an 8-in. diameter objective. The monochromator consists of a reflexion grating (Bausch and Lomb, 2,160 lines/mm, blazed for 3000 Å, ruled area 52 mm × 52 mm) in an Ebert mounting. Filters of nickel sulphate solution combined with Chance $OX.7$ glass are mounted immediately in front of the photomultipliers; these very effectively cut out stray light of greater wave-length scattered within the monochromator, and, indeed, a strong room light can be used while observations are in progress with no influence on the counting rate.

Accurate control of the wave-length setting is achieved by use of a mercury lamp, and all variations in photometric sensitivity are eliminated by the use of a standard lamp.

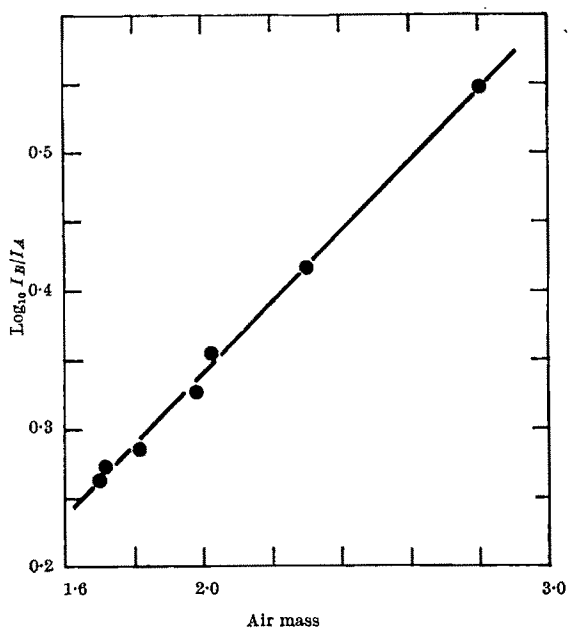

Fig. 1. Observations of ε-Ori on January 17, 1963

Observations of a number of bright stars have been made at Cambridge during the winter and spring 1962–3 in order to test the equipment. A typical example is shown in Fig. 1, in which the wave-bands were *A*: 3100–3150 Å, *B*: 3220–3250 Å. The 'exposure' time was 40 sec. The amount of ozone derived from the slope of the least-squares line shown is (402 ± 12) m atm. cm (standard error), using the data of Vigroux[14] for ozone absorption and of Cabannes[15] for Rayleigh scattering.

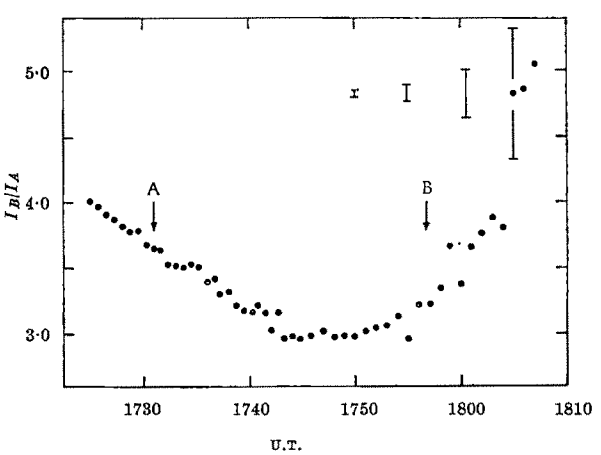

Fig. 2. Ratio of zenith sky brightnesses in the two wave-bands (ozone absorption greater in *A*) on February 26,1963. The ratio has already passed through a maximum (the normal *umkehr* or inversion point) before observations started. The minimum at approximately 1747 h is the so-called second *umkehr*. *A* indicates sunset and *B* the time at which the Sun was 4 deg below the horizon. The standard error of a single point, based on the statistical distribution of photons, is indicated by the vertical lines

If the instrument is pointed at the clear zenith sky the usual *umkehr* observation can be made as the Sun sets or rises. The necessary reduction of sensitivity can be achieved by placing perforated screens over the telescope. Fig. 2 shows the last stages of such an observation (no perforated screens) and shows clearly the 'second Umkehr' which has been reported by Ramanathan[16] and Dütsch[17]. Whether these measurements will prove useful for the determination of vertical ozone distributions in arctic regions is being investigated. We acknowledge the support received for this work from the Meteorological Office.

METALLURGY

A Technique for producing Regular Patterns on Single Crystals

To examine the deformation of single crystals, it is often necessary to have regularly spaced marks or a grid on the surface of the specimen. In particular, the analysis of plastic strains is carried out by investigating the distortion of the grid using the intersections of the lines as reference points. There are several methods for producing a grid, but usually only one of the following two is used: (1) scratching accurately spaced lines; (2) photo-engraving the required pattern. Both are laborious and require great care in their application. All the methods known to authors subject the specimen to a certain amount of deformation. This affects only the surface of a polycrystalline specimen and can be completely disregarded except when the surface processes themselves are investigated. On the other hand, the mechanical properties of single crystals are extremely sensitive to surface effects. On this account, none of the existing methods was considered satisfactory. It is the purpose of this communication to report a technique which was developed for producing regular patterns on single crystals without subjecting the specimen to any strain.

The surface of the specimen has to be reasonably smooth to obtain distinct marks at the required spacing. While no specific directives can be given for the surface roughness, it is useful to note that satisfactory grids (Fig. 1) were produced without any mechanical or chemical surface preparation for the strain analysis of zinc single crystals, grown from the melt in graphite boats.

A silk screen, having the required pattern and stretched tautly in a light frame, was placed on the specimen surface. The screen was of the type used in the textile silk printing process. Next, the silk was covered uniformly with undiluted screen printing paint. The paint penetrated through the silk and, when the screen was lifted from the specimen, a regular pattern was left on the surface. After 24 h, when the paint was completely dry, the crystal was etched (Fig. 1). Etching was necessary because the paint could not be relied on to follow completely the deformation. The etchant attacks the metallic surface producing a relief pattern. We have found the etchants reported in Table 1 suitable for zinc and copper specimens.

Table 1

Crystal	Etchant
Zn	1_P HCl; 1_P CH_3COOH glacial
Cu	1_P HNO_3; 1_P H_2O

The depth of the marks was controlled by the etching time and for zinc and copper this was in the order of 10 sec. If the specimen is over-etched, the grid becomes irregular. Over-etching can also lift off the paint, distorting the already developed pattern. The etching can be stopped at any time by rinsing in water and resumed, if necessary, without any harmful effect.

An example of a grid produced on a zinc specimen is shown in Fig. 1. The lines are 0·3 mm apart and are estimated to be approximately 0·05 mm deep. It is believed that with this method a grid as fine as 20 lines/mm can be produced easily.

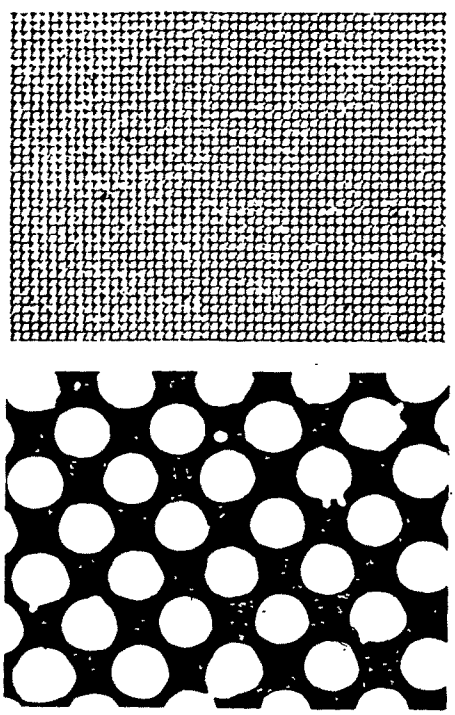

Fig. 1*a* (C × 4) and *b* (C × 30) illustrate two of the many possible patterns. A wide variety of patterns can be produced by different combinations of paint density and thickness

This technique was originally developed for the stress analysis of single crystals, since it was found that, when the strains are known, the stresses can be calculated from the differential equation:

$$\frac{\partial^3\varphi}{\partial y^3}\frac{\partial\varepsilon_x}{\partial x} - \frac{\partial^3\varphi}{\partial x\partial y^2}\frac{\partial\varepsilon_x}{\partial y} + \frac{\partial^3\varphi}{\partial x^2\partial y}\frac{\partial\varepsilon_y}{\partial x} - \frac{\partial^3\varphi}{\partial x^3}\frac{\partial\varepsilon_y}{\partial y} + \frac{\partial^3\varphi}{\partial x\partial y^2}\frac{\partial\gamma_{xy}}{\partial x} - \frac{\partial^3\varphi}{\partial x^2\partial y}\frac{\partial\gamma_{xy}}{\partial y} = 0$$

where ε_x, ε_y, γ_{xy} are the normal and shear strains in the x and y directions respectively. φ is the Airy stress function[1].

The strains were determined experimentally by using the technique described here. For this stress analysis the pattern shown in Fig. 1 was eminently satisfactory. The development of the equation will be reported elsewhere.

CHEMISTRY

Ionization Potentials and the Structures of the Photo-ionization Yield Curves of Ethylene and its Halogenoderivatives

The problem of interpreting the differences between ionization potentials obtained by electron (E.I.) and by photon impact (P.I.) has led us to a careful examination of the structures occurring in the photo-ionization yield curves of *cis* and *trans* dichloro- and dibromoethylenes[1-3]. The regularly spaced structures found in these curves have been interpreted in terms of vibrational progressions involving the C—C valence vibrations of the ions.

Investigations have been carried out on the foregoing substances, on ethylene itself and on many halogenated derivatives by both P.I. and E.I. techniques. Ion-yield curves have been obtained over the range from the ionization thresholds up to 11·2 eV. The ionization potential by E.I. was obtained by treating the ionization curve as suggested by Warren[4]. The first differential treatment of Hurzeler, Inghram and Morrison[5] has been applied to the P.I. curves for the determination of ionization potentials and to the analysis of the structural details in these curves.

Table 1

Substance	E.I. (eV.)	P.I. (eV)	Difference
C_2H_4	10·56 ± 0·05	10·50 ± 0·02	0
C_2H_3Cl	10·10 ± 0·03	10·00 ± 0·02	0·10
C_2D_3Cl	10·10 ± 0·03	10·02 ± 0·02	0·10
C_2H_3F	10·45 ± 0·05	10·37 ± 0·02	0·08
C_2H_3Br	9·97 ± 0·05	9·82 ± 0·02	0·15
1–1$C_2H_2F_2$	10·32 ± 0·05	10·31 ± 0·02	0
cis $C_2H_2Cl_2$	9·66 ± 0·05	9·66 ± 0·02	0
trans $C_2H_2Cl_2$	9·96 ± 0·05	9·64 ± 0·02	0·36
cis $C_2H_2Br_2$	9·69 ± 0·05	9·45 ± 0·02	0·14
trans $C_2H_2Br_2$	9·54 ± 0·05	9·46 ± 0·02	0·08
cis CHF = CHCl	10·14 ± 0·03	9·86 ± 0·02	0·28
trans CHF–CHCl	10·30 ± 0·03	9·87 ± 0·02	0·43
cis CHF = CFCl	10·17 ± 0·03	9·86 ± 0·02	0·31
trans CHF = CFCl	9·96 = 0·03	9·83 ± 0·02	0·13

The results for the threshold values and also the differences between E.I. and P.I. measurements are given in Table 1. A comparison of the photo-ionization curves for C_2H_3Cl and C_2D_3Cl confirms the interpretation of the structures of these curves in terms of ionization to vibrating states of the ion involving C—C valence vibrations and provides a strong basis for similar interpretations in other compounds. There is some evidence also for the simultaneous excitation of torsional vibrations about the C—C bond.

New data have been found on spin-orbit splitting in the ions containing chlorine and bromine atoms and on electronically excited states existing between the ionization threshold and 11·2 eV. The results are summarized in Table 2.

Table 2

Substance	Doublet separation (cm^{-1})	(C—C) ion (cm^{-1})	Other frequencies (cm^{-1})	Excited electronic states (eV)
C_2H_4	—	1,463	470 (torsion)	—
C_2H_3Cl	990	1,230		10·515
C_2H_3F		1,290		10·880
C_2H_3Br	2,419	1,170	260 (torsion)	10·300
1–1$C_2H_2F_2$		1,371	605 (?)	10·890
1–2$C_2H_2Cl_2$	1,050	1,432		10·275; 10·50; 10·74
1–2CHF = CHCl	1,130	1,412		10·30
1–2CHF = CFCl	1,130	1,412		10·43; 10·82
1–2CHBr = CHBr	2,621	1,210	400	9·84

The wide photon energy range used enabled me to detect in the photo-ionization yield curves a number of sharp peaks in addition to the successive step functions characterizing vibrational excitation in the ions. These have been correlated with strong absorption bands present above the first I.P. (for example, in C_2H_3Cl) and interpreted as excited states of the molecules situated above the ionization threshold and, therefore, subject to non-radiative transitions to the ionization continuum (that is, by auto-ionization). A more detailed study of these states will be published later.

The correlation of the vibrationally and electronically excited states observed for the ions with the differences between E.I. and P.I. ionization potentials in Table 1 strengthens my previous opinion that E.I. ionization potentials correspond to the most probable transition to the ionized state (vertical I.P.). The nature of this probable transition leading to any vibrationally or electronically excited state of the ion is shown in Table 3.

Table 3

Substance	Difference E.I.—P.I. (V)	Vertical transition to:
C_2H_3Cl	0·10	v = 0 of the second level of the doublet
C_2H_3Br	0·15	v = 1 of the C—C vibration
trans CHCl=CHCl	0·36	v = 1 level of the C—C vibration of the second level of the doublet
cis CHBr=CHBr	0·14	v = 1 level of the C—C vibration
trans CHBr=CHBr	0·08	v = 1 level of the 400 cm^{-1} vibration
cis CHF=CHCl	0·28	v = 1 level of the C—C vibration of the second level of the doublet
trans CHF=CHCl	0·43	v = 0 of the first electronic excited state of 10·275 volts
cis CHF=CFCl	0·27	v = 1 level of the C—C vibration of the second level of the doublet
trans CHF=CFCl	0·11	v = 0 of the second level of the doublet

I am grateful to Prof. W. C. Price for permission to use his vacuum grating monochromator in spring 1961 and in autumn 1962. I also thank the British Council, the Royal Academy of Belgium, the Fonds National de la Recherche Scientifique and the Patrimoine de l'Université de Liège for financial support during my stay in King's College, London. I thank Prof. L. d'Or for his interest in this work.

Molecular Geometry of 7α-Bromocholesteryl Chloride

The crystal and molecular structures of 7α-bromocholesteryl chloride, $C_{27}H_{44}ClBr$ (Fig. 1), were determined by Bürki and Nowacki[1] in 1956 by single crystal X-ray diffraction analysis using a combination of heavy atom, isomorphous replacement, and Patterson superposition methods. The unit cell is monoclinic, space group $P2_1$ with cell constants of a_0 = 11·95 Å, b_0 = 8·78 Å, c_0 = 12·54 Å, β = 101·2°, and Z = 2.

The fractional atomic co-ordinates (x, y, z) obtained by Bürki and Nowacki have been converted to Cartesian co-ordinates p, q, r in Å units, where $p = xa_0 \sin \beta$, $q = yb_0$, and $r = zc_0 + xa_0 \cos \beta$, and used to calculate various intra-molecular relationships. The method of Schomaker *et al.*[2] has been used to compute a series of equations for the 'best' planes to which various atomic groupings may be referred (Table 1). The root mean square (r.m.s.) distances of atoms from these planes are listed in Table 2. Inter- and intra-ring dihedral angles are set forth in Table 3, and the perpendicular distances of individual atoms from one or more 'best' planes are given in Table 4.

The 'best' plane obtained when all 27 carbon atoms of 7α-bromocholesteryl chloride are considered has the equation: $0{\cdot}31x - 0{\cdot}86y + 0{\cdot}41z = 1{\cdot}32$. The r.m.s. distance of carbon atoms from this plane is 0·57 Å. If only the steroid nucleus, C_1 through C_{17}, is considered, the 'best' plane has the equation: $0{\cdot}26x - 0{\cdot}90y + 0{\cdot}35z = 1{\cdot}07$, with a r.m.s. distance of 0·28 Å. It is interesting to note that a similar spatial distribution of atoms is evident in cholesteryl iodide[3], where the r.m.s. distance value is 0·58 Å for the 27 carbon atom plane, and 0·28 Å for the plane of the steroid nucleus (C_1—C_{17}).

Rings *A*, *B*, *C* and *D* have a higher degree of planarity than either the entire carbon-atom molecule or the steroid nucleus, as can be seen by their r.m.s. distances of 0·22, 0·26, 0·23 and 0·20 Å respectively. Since the atomic co-ordinate standard deviation obtained by Bürki and Nowacki is approximately 0·03 Å, it is evident that the degrees of planarity of the 'best' planes representing rings *A*, *B*, *C* and *D* are approximately equal.

Table 4. PERPENDICULAR DISTANCE (Å) OF ATOMS FROM ONE OR MORE OF THE 'BEST' PLANES OF 7α-BROMOCHOLESTERYL CHLORIDE

Br_7	2·28	2·26			+1·97								

Smaller deviations from planarity occur in the *A*2, *B*2, *C*2 and *D*2 portions of the 7α-bromocholesteryl chloride molecule, which have r.m.s. distances of 0·03, 0·17, 0·02 and 0·14 Å respectively. In view of the 0·03 Å standard deviation, it is seen that in this case the degree of planarity of *A*2 equals that of *C*2, and that the degree of planarity of *B*2 equals that of *D*2.

Table 3 lists the dihedral angles of 7α-bromocholesteryl chloride (standard deviation is approximately 1·4°). Within the limits of the standard deviation, it can be seen that $B \wedge C$ equals $C \wedge D$, $A2 \wedge A3$ equals $A3 \wedge B1$, and $C1 \wedge C2$ equals $C2 \wedge C3$.

The following features of side-group geometry may be deduced from Table 4, which lists the perpendicular distance of atoms from one or more of the 'best' planes:

(1) The chlorine atom attached to C_3 is equatorial.

(2) The bromine atom attached to C_7 has an axial configuration, and is nearly perpendicular to the 'best' plane of the steroid nucleus. The evidence for this is that the perpendicular distance of the bromine to the 'best' plane of the steroid nucleus (2·26 Å) is equal to the sum of the C_7-Br bond length and the perpendicular distance of C_7 to the 'best' plane of the steroid nucleus.

(3) The bromine atom and the angular methyl groups (C_{18} and C_{19}) are on opposite sides of the steroid nucleus as can be seen from the change in sign of their respective perpendicular distances from the 'best' plane of the steroid nucleus. (Atoms lying between the origin of the unit cell and the 'best' plane have a negative value; those on the opposite side of the plane have a positive value.)

(4) The C_{18} and C_{19} angular methyl groups are axial, and almost perpendicular to the 'best' plane of the steroid nucleus. The evidence for this is that in both cases the perpendicular distance of the atom in question is equal to the sum of the appropriate methyl carbon–nuclear carbon bond length and the perpendicular distance of the appropriate nuclear carbon to the 'best' plane of the steroid nucleus.

Recombination of Chlorine Atoms

THE rate of recombination of chlorine atoms has been investigated using a flow system. The atoms were produced in a microwave discharge, and the atom decay followed by means of a movable thermocouple probe at which recombination occurred. The reaction tube of 4-cm internal diameter was poisoned with boric oxide. Runs using chlorine only, and chlorine/argon mixtures, were carried out. Linear flow speeds in the range 30–250 cm/sec, and total pressures (measured with a sloping oil manometer) of 0·24–3 mm mercury were used.

At low chlorine pressures, a first-order decay in the chlorine atom concentration was observed. This was attributed to surface recombination. Ogryzlo[1] has previously studied this. As the chlorine pressure was raised, the order increased towards two. The following mechanism is proposed to account for these observations:

$$\mathrm{Cl} + \mathrm{wall} \xrightarrow{k_w} \tfrac{1}{2}\mathrm{Cl}_2 + \mathrm{wall}$$

$$\mathrm{Cl} + M \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} \mathrm{Cl}M$$

$$\mathrm{Cl}M + \mathrm{Cl} \xrightarrow{k_2} \mathrm{Cl}_2 + M$$

Assuming an equilibrium concentration of the intermediate Cl*M*, the resulting rate equation can be integrated to give:

$$k_w t = \ln\left[\frac{[\mathrm{Cl}]_0}{[\mathrm{Cl}]_t}\right] + \ln\left[\frac{k_w + k[\mathrm{Cl}]_t[M]}{k_w + k[\mathrm{Cl}]_0[M]}\right] \qquad (1)$$

where

$$k = \frac{k_1 k_2}{k_{-1}}$$

The agreement between the experimental data for runs with chlorine only and this theoretical expression is demonstrated in Fig. 1. If a reasonable value is assumed for the percentage dissociation of chlorine, a value of approximately 6×10^{14} c.c.^{2} mole^{-2} sec^{-1} is derived for the *ter*molecular rate constant k_{Cl_2} defined by

$$-\frac{\mathrm{d}[\mathrm{Cl}]}{\mathrm{d}t} = k_{\mathrm{Cl}_2}[\mathrm{Cl}]^2[\mathrm{Cl}_2]$$

This constant implies that, a few centimetres from the discharge, the percentage dissociation was 1 per cent at 1 mm, 10 per cent at 0·5 mm., and 35 per cent at 0·25 mm pressure. These percentages are unlikely to differ by more than a factor of two from the actual values, so that

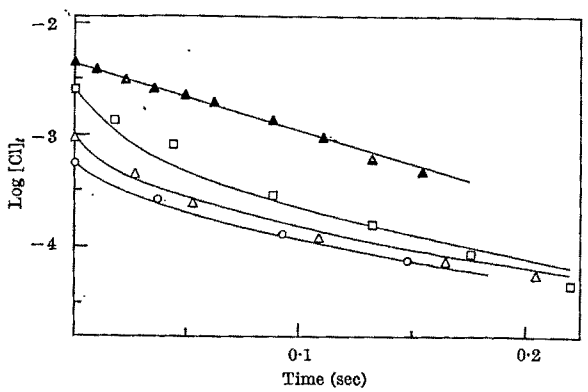

Fig. 1. Variation of log [Cl]$_t$ with time, using 100 per cent chlorine. ▲, at pressures of 0·25 mm; □, 0·5 mm; △, 0·775 mm; ○, 1·05 mm. The points are experimental; the lines are theoretical (equation (1))

the probable range of values for the rate constant is $3–12 \times 10^{14}$ c.c.^{2} mole^{-2} sec^{-1}.

From the experiments with argon/chlorine mixtures the qualitative conclusion can be drawn that argon is less efficient as a third body than chlorine for the recombination reaction; the observed reaction order remained one for all mixtures, and with particular significance for those having a high total pressure but a low partial pressure of chlorine.

The first-order rate constant, k_w, was found to vary inversely with the total pressure, implying control by radial diffusion. Using a calculated value for the diffusion coefficient[2] this would not be expected; the calculated coefficient for chlorine atoms may therefore be too high. Ogryzlo gives a value of 4×10^{-5} for γ, the surface recombination coefficient. In the present experiments, γ was probably of the order of 10^{-3}, but this could not be determined reliably since the first-order rate constant was not found to be independent of pressure. Further work is being carried out in this laboratory.

Hydrogen – Air Fuel Cell with Homogeneous Oxidation Catalyst Redox Cycle

In fuel cells with an intermediate redox cycle, electrochemical reactants are prepared by the action of a fuel and an oxidant on a redox system. Complexes of copper in certain organic solvents present particularly interesting systems. For example, cupric acetate dissolved in pyridine oxidizes molecular hydrogen; cuprous acetate is the homogeneous catalyst as well as the reaction product[1,2]. In air, the reverse reaction proceeds with ease. Such systems may be useful in fuel cells operating on air and hydrogen as they would avoid the troublesome problem of maintaining the gas/electrolyte boundary in a specific position in the porous electrodes.

I carried out experiments to estimate the properties of such a system. Hydrogen at 95° C and atmospheric pressure reduced a 0·2 M solution of cupric acetate in pyridine without the formation of copper metal. Cells composed of platinum/copper^{II}/pyridine acetate/copper^{I}/platinum, where copper^{II} and copper^{I} stand for the solutions of the corresponding acetates in pyridine, yielded 0·21–0·24 V at 95° C. With a silver anode the potentials were 0·01–0·03 V higher. Carbon dioxide and carbon monoxide did not affect the anode potential. Hence the system should be able to utilize hydrogen from water gas, or hydrocarbon-reforming gas, without need for prior removal of carbon oxides. After polarization by drawing currents, the potential recovered readily. The potential of the cathode was 0·06 V noble versus a saturatep calomel electrode, measured by disregarding liquid junction potentials that may be associated with the pyridine acetate bridge.

Although the potential of this cell was low, compared with 0·95–1·10 V for direct hydrogen–oxygen fuel cells, other complexing and solvent media may give more favourable potentials.

BIOCHEMISTRY

Blood Corticosterone-levels in the Rat after Administration of Amino-acids

Munro and Mukerji[1] observed that the feeding of single large doses of certain individual amino-acids, notably glycine, methionine and leucine, caused a marked stimulation of uptake of phosphorus-32 by rat-liver ribonucleic acid (RNA) during the next 18 h. In the case of methionine and leucine, but not of glycine, this action was abolished by adrenalectomy[2]. It was therefore proposed that the increased incorporation of phosphorus-32 into liver RNA after feeding methionine or leucine was due to release of adrenocortical hormones, which are known to induce changes in liver RNA metabolism[3]. The experiments reported here show that, within a 24-h period of administering methionine or leucine to rats, there is an elevation of blood corticosterone-level. Administration of other amino-acids or of casein does not have this effect. These observations would thus appear to confirm the proposed mechanism of action of methionine and leucine on liver RNA metabolism.

Male rats weighing about 150 g, trained[1] to consume food promptly, were fed a meal containing 2 g of a starch-glucose mixture[1] and 1 g of an amino-acid (glycine, methionine, leucine, alanine, aspartic acid or glutamic acid) or casein; control animals received the starch-glucose mixture without any addition. All animals were killed 24 h later by guillotine and corticosterone concentrations in the plasma and the adrenal glands were measured fluorometrically[4] with an Aminco-Bowman spectrophotofluorometer.

Table 1. Corticosteroid-levels in Plasma and Adrenal Gland 24 h After Feeding Individual Amino-acids or Casein in 1-g Quantities to Rats

Addition to carbohydrate meal	Corticosterone concentration in plasma	Corticosterone concentration in adrenal gland
Casein	86	110
Glycine	85	110
Methionine	125	139
Leucine	107	131
Alanine	80	122
Aspartic acid	82	119
Glutamic acid	76	108
By analysis of variance	$P < 0·01$	$P > 0·05$
Fiducial limits	28	—

The results are expressed as a percentage of corticosterone concentration found in plasma or gland 24 h after feeding the carbohydrate meal alone.

The control animals fed only the carbohydrate meal had high levels of corticosterone in the plasma (mean level 126 μg/100 ml. plasma) and in the adrenal glands (mean concentration 9·5 μg/100 mg adrenal tissue), compared to the values reported in the literature[4,5]. Rats taken directly

from stock cages had much lower levels, and the high concentrations observed in the experimental group can be attributed to partial undernutrition during the training period. It is thus not surprising that the addition of casein and of several of the amino-acids to the carbohydrate test meal lowered the plasma corticosterone concentration found 24 h after the meal (Table 1), since these substances would serve as sources of additional energy for the animal. In contrast, methionine and leucine raised the plasma concentration of corticosterone, and analysis of variance confirmed that the effect of these two amino-acids differed significantly from that of other amino-acids administered. Amino-acid feeding caused no depletion of adrenal corticosterone content, and even tended to raise the level, particularly after methionine and leucine administration (Table 1), though none of these increments attained statistical significance. Subsequent experiments not presented here show that prolonged administration of leucine and methionine results in considerable increases in corticosterone concentration in the gland.

Action of Insulin on the Isolated Rat Diaphragm in the Presence of Actinomycin *D* and Puromycin

Within recent years, conclusive evidence has been obtained of a direct stimulation of transport of sugar from the extracellular to the intracellular space of the isolated perfused heart of the rat[1] and the isolated 'caged' diaphragm of the rat[2]. It is, however, difficult to explain the entire mechanism of insulin action through this effect, for clear-cut insulin-induced stimulations have been observed in the absence of extracellular or intracellular glucose: these effects include biosynthesis of proteins from labelled precursors[3], increased labelling of RNA from ^{14}C-adenine or glucose[4] and increased specific labelling of high-energy phosphates from intracellular inorganic phosphate labelled with phosphorus-32 (ref. 5). This evidence raised the question[4] whether an induced biosynthesis of messenger RNA (ref. 6), which could in turn stimulate the synthesis of specific enzymatic proteins, may participate in the hormonal action; recent work on the effects of other hormones[7,8] supports this hypothesis.

As the biosynthesis of RNA may be selectively inhibited by actinomycin *D* and inhibition of protein biosynthesis occurs with puromycin in mammalian cells, an investigation was undertaken with these inhibitors on different insulin-stimulated phenomena in the isolated rat diaphragm. Three tests were performed in the absence of glucose, namely, RNA and protein biosynthesis from ^{14}C-labelled precursors and labelling of energy-rich compounds from ^{32}P inorganic phosphate; the fourth test consisted of the measurement of glucose uptake.

The incubation method and the separation of the labelled phosphate fractions have been previously described[5]. The isolation of RNA and the estimation of its radioactivity have been performed as described by Wool[4]; the incorporation of labelled 1-^{14}C-adenine into ATP, considered to be a direct precursor of RNA, is measured in a similar manner as incorporation of ^{32}P into ATP (ref. 5). The incorporation of labelled amino-acids (U-^{14}C-protein hydrolysate or 1-^{14}C-D,L-valine) is performed according to Manchester[3]. The specific radioactivities of the extracellular and intracellular amino-acid pools are measured on the TCA-soluble extracts of the incubation medium or the diaphragm, free amino groups being determined by a ninhydrin-method, on the assumption that the average nitrogen content of these pools is 16 per cent; however, when ^{14}C-valine was used, the precursor pools are expressed as counts per unit weight of the incubation medium or the diaphragm.

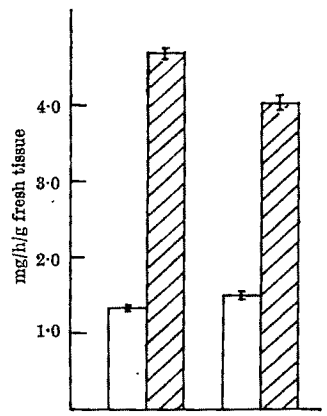

Fig. 1. Influence of puromycin on the uptake of glucose of the isolated diaphragm of the rat in absence (white) and presence (hatched) of insulin (10 μg/ml.). Left, no puromycin; right, puromycin (500 μg/ml.). Standard error of the mean indicated at the top in each case

Actinomycin *D* and puromycin dichlorhydrate are added at the beginning of the experiment and pre-incubation in the presence of these antibiotics lasted 30 min. The labelled precursors (^{32}P inorganic phosphate: 10–20 μc., ^{14}C substrates: 1 μc.) or the unlabelled glucose (2 mg/ml.) are then tipped into the incubation medium. Glucose uptake, protein and RNA labelling are measured over 2-h periods, whereas the labelling of phosphates is determined over periods of 10 min; control experiments showed that if the labelling of these phosphates is measured after pre-incubations of 2 h, the effects of insulin, puromycin and actinomycin *D* are not modified.

Table 1 shows that RNA synthesis from labelled adenine is enhanced by almost 100 per cent in the presence of insulin. Despite complete inhibition of RNA labelling by actinomycin *D*, it appears (Table 1) that labelling of protein is unchanged in presence of this antibiotic; stimulation by insulin averages 100 per cent both in its presence and in its absence. Labelling of ATP from adenine is unchanged in all cases.

Table 2 shows the effect of actinomycin *D* and puromycin on the labelling of energy-rich phosphates and its stimulation by insulin: no inhibition is detected under experimental conditions, where RNA biosynthesis is completely inhibited by actinomycin *D* (Table 1) and where the labelling of proteins is completely suppressed by puromycin (Table 3). Hence the glucose-independent metabolic stimulation by insulin, which is reflected in the turnover of these nucleotides, does not depend on protein or RNA biosynthesis.

Finally, Fig. 1 shows that enhancement of glucose uptake by insulin is independent of protein biosynthesis, as puromycin has no detectable effect on this phenomenon.

From these results, two-fold conclusions may be drawn: first, it appears that labelling of RNA and proteins from ^{14}C precursors[3,4] are sensitive to specific inhibitors and thus represent true biosynthesis of these molecules; this is apparent even when the precursor is valine, the penetration of which into the cell is not sensitive to insulin stimulation[3]. It is also noteworthy that the inhibitions by actinomycin *D* or puromycin are complete after 30 min. Hence it appears that the penetration of these compounds into the cell is not a limiting factor for their efficiency.

Table 1. Influence of Actinomycin *D* on the Insulin-induced Stimulation of the Biosynthesis of RNA and Protein in the Isolated Rat Diaphragm

Actinomycin *D* (10 μg/ml.)	0	0	+	+
Insulin (10 μg/ml.)	0	+	0	+
A Biosynthesis of RNA from (8-^{14}C) adenine				
ATP (counts/μg)	201	212	207	280
RNA fraction (counts incorporated/100 mg tissue)	1,006	2,040	26	38
B Biosynthesis of proteins from (U-^{14}C) protein hydrolysate				
Extracellular amino-acid pool (counts/μg)	319	374	327	399
Intracellular amino-acid pool (counts/μg)	66	71	69	72
Proteins (counts/mg)	316	706	395	765

Table 2. Influence of Actinomycin *D* and Puromycin on the Insulin-induced Stimulation of the Labelling of Phosphates in the Isolated Rat Diaphragm

Specific activity (percentage of extracellular or intracellular phosphorus)							
Actinomycin *D* (10 μg/ml.)		0	0	+	+	0	0
Puromycin (500 μg/ml.)		0	0	0	0	+	+
Insulin (10 μg/ml.)		0	+	0	+	0	+
Intracellular inorganic phosphorus	(*E*)	6·9	6·2	7·2	6·7	8·7	10·7
PC*	(*I*)	35·8	44·4	32·7	53·3	31·4	40·5
ATP	(*I*)	44·5	58·5	40·2	68·0	43·4	70·0
ADP	(*I*)	19·7	24·5	19·5	30·2	17·9	21·7
U + G†	(*I*)	24·4	37·9	26·2	51·5	16·7	32·5

(*E*) Percentage of extracellular inorganic phosphorus.
(*I*) Percentage of intracellular inorganic phosphorus.
* Phosphocreatine.
† Sum of uridine and guanosine phosphates.

Table 3. Influence of Puromycin on the Insulin-induced Stimulation of Protein Biosynthesis in Isolated Rat Diaphragm

A Precursor: U-^{14}C protein hydrolysate				
Puromycin (500 μg/ml.)	0	0	+	+
Insulin (10 μg/ml.)	0	+	0	+
Extracellular amino-acid pool (counts/μg)	940	740	545	518
Intracellular amino-acid pool (counts/μg)	115	120	152	131
Proteins (counts/mg)	750	1,371	24	11
B-Precursor: D,L -1^{14}C Valine				
Incubation medium (counts/100 mg)	7·800	8·800	—	8·767
Intracellular medium (counts/100 mg)	6·300	5·745	—	6·352
Proteins (counts/mg)	166	213	—	1

The second set of conclusions concerns the mutual independence of the phenomena which have been tested. This independence is particularly striking so far as protein and RNA biosynthesis are concerned: the complete suppression of the latter has no influence whatsoever on the stimulation of the former; thus it seems difficult to conclude[4] that the biosynthesis of a messenger RNA could even partially mediate the action of insulin on the isolated muscle.

Hence this action seems to consist in a general stimulation of uncorrelated metabolic events; the insulin-induced increase of glucose-uptake may, however, be inhibited by short pre-incubations with *N*-ethylmaleimide[9]. This equally holds for the labelling of energy-rich phosphates[10] and demonstrates that an interaction of insulin with specific —SH groups is a pre-requisite for its effect on the isolated muscle, the precise mechanism of which (for example, cell 'decompartmentation') remain at present a matter of speculation.

Naphthalenes in Cigarette Smoke

In our work on the composition of the non-methanol volatile neutral fraction of cigarette smoke we have isolated and identified the naphthalenes shown in Table 1.

Table 1

Substance	Yield*
Naphthalene	0·17
2-Methylnaphthalene	0·50
1-Methylnaphthalene	0·50
2,7-Dimethylnaphthalene	0·26
2,6-Dimethylnaphthalene	0·26
1,6-Dimethylnaphthalene	1·30
1,3,6-Trimethylnaphthalene	0·70

* In μg/cigarette (average weight, 1·15 g)

The naphthalenes were isolated from chromatographic fractions of cigarette smoke condensate by precipitation as complexes with *s*-trinitrobenzene. The combined complexes were decomposed and the mixture of naphthalenes obtained was separated by preparative scale gas chromatography. The individual naphthalenes were identified by comparison of ultra-violet and infra-red spectra with those of authentic specimens and by the preparation of solid derivatives. Analytical gas chromatography showed that these were the only naphthalenes present (eluted in the order shown in Table 1) except for a small shoulder appearing on the peak corresponding to 1,6-dimethylnaphthalene. The retention volume of this shoulder corresponded to 1,8-dimethylnaphthalene and/or acenaphthene. Naphthalene, 2-methylnaphthalene, and possibly 1,8-dimethylnaphthalene have been detected already by ultra-violet spectroscopy[1,2]. Acenaphthylene, reported earlier[1], occurs in a later chromatographic fraction of the smoke condensate. The relatively large quantities of dimethyl- and trimethylnaphthalenes have escaped detection by methods used previously, but their presence gives an important lead to the understanding of the mode of formation of polycyclic hydrocarbons in cigarette smoke. The positions of the methyl groups indicate terpenoid precursors of these naphthalenes, and an extension of the suggested mode of thermal decomposition of isoprenoid polyolefines[3] can account fully for their formation.

Boric Acid-induced Heterogeneity of Conalbumin by Starch-gel Electrophoresis

Multiple molecular forms of conalbumin[1], the iron-binding component of avian egg white, have been described by numerous investigators under a variety of experimental conditions. In the original purification of conalbumin, Longsworth *et al.*[2] identified two components, the relative proportions of which were dependent on *p*H. Afterwards, by starch-gel electrophoresis, Lush[3] identified two, and occasionally three, iron-binding proteins in native egg white, as did Williams[4] and Ogden *et al.*[5]. In each of these cases[3–5], the slower migrating of the two components was the more intense; in the latter investigations[4,5] a corresponding heterogeneity was observed in transferrin, the iron-binding protein in the serum of the animal. Thus, in the chicken, as in other species, including man[6], primates[7], cattle[8,9], bison[10], horses[11], and mice[12], a single transferrin allele appears to determine the synthesis of more than one molecular species of transferrin. Ultracentrifugal investigations on purified cattle transferrins indicate that the multiple bovine components do not represent a polymer series[13].

Ogden *et al.*[5] have also described a genetically determined variation in chicken serum transferrin which is

paralleled by a corresponding variation in the conalbumin pattern, and Williams[4] has suggested that the avian transferrin gene may determine the synthesis of both transferrin (in the liver) and conalbumin (in the oviduct). Williams[4] has also investigated the biochemical relationship between transferrin and conalbumin and has proposed that these proteins may differ only in their sialic acid content. A similar phenomenon has been described in human cerebrospinal fluid[14], where two principal transferrins have been observed, one with the full serum complement of four sialic acid residues per molecule and the other devoid of sialic acid. However, in this case the difference appears to involve more than the sialic acid moiety and may represent the absence of multiple-unit carbohydrate prosthetic groups on the transferrin molecule[15].

This communication presents evidence for an artificially induced heterogeneity of conalbumin as revealed by starch-gel electrophoresis in boric acid buffer systems. Similar results have been obtained both for conalbumin in filtered egg white and for purified conalbumin. The purification of conalbumin was accomplished by a two-step procedure involving starch-block electrophoresis and cellulose chromatography, as previously utilized for the purification of human and primate transferrins[14]. In the final step, the conalbumin fraction from 20 ml. egg white separated by preparative electrophoresis in a starch-granule block was applied to a TEAE cellulose column. In 0·015 M disodium hydrogen phosphate buffer, only iron-binding components (conalbumins) were eluted from the column. Vertical starch-gel electrophoresis was carried out according to the method of Smithies[16], and iron-binding components were detected by autoradiography after addition of iron-59 to the samples[17].

The starch-gel pattern observed for conalbumin revealed multiple iron-binding components. In *tris*-citrate (*p*H 8·8) and phosphate-citrate (*p*H 7·4) buffers, a single prominent relatively slow-migrating component was observed, together with two, and occasionally three, faint, more rapidly migrating components. This is essentially the same conalbumin pattern as described by Lush[3], Williams[4], and Ogden *et al.*[5], who each utilized the *tris*-citrate[18] buffer system.

In boric acid–sodium hydroxide buffers, however, two additional prominent components were observed the presence and relative intensity of which depended on the concentration of conalbumin and on the concentration and *p*H of the borate buffer (Fig. 1). At low protein concentrations and low boric acid concentrations (that is, at high *p*H, where a large proportion of the boric acid was neutralized by sodium hydroxide, or in dilute buffers), only a single prominent component was present which appeared to correspond to the major component observed in the *tris*-citrate and phosphate-citrate buffers. When the protein concentration or boric acid concentration was increased, the major component split into a second slower migrating component, which in turn gave rise, with considerable trailing, to a third slower-migrating component. This third component did not bind radioactive iron. The observed patterns were independent of the amount of iron added to the sample.

The two additional boric acid-induced components were present in undiluted egg white after electrophoresis in the conventional borate buffer of Smithies[16] (0·020 M metaboric acid, 0·0084 M sodium hydroxide; *p*H 8·9). At a one-eighth dilution of the egg white, only the single component was observed; reconcentration of the diluted material resulted in the reappearance of the three components (Fig. 1). The band corresponding to the slowest moving non-iron binding boric acid-induced conalbumin component was removed from an unstained slice of the starch gel and the protein was eluted by freezing and thawing. By a second electrophoresis at an appropriate dilution, this component bound radioactive iron; its mobility was increased and coincided with the single prominent conalbumin component in diluted egg white.

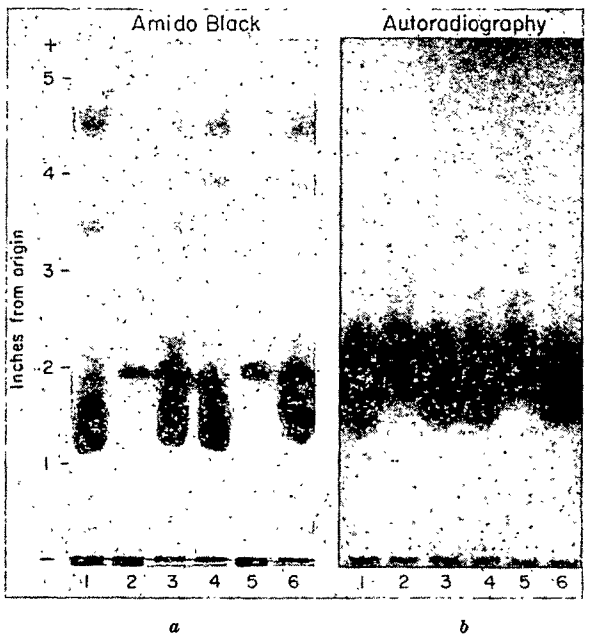

Fig. 1. Boric acid-induced heterogeneity of conalbumin in egg white. 1,4: egg white, undiluted; 2, 5: egg white, diluted 1 : 8; 3, 6: egg white, diluted and reconcentrated

(*a*) Amido black stain after vertical starch-gel electrophoresis. Gel buffer: 0·020 M H_3BO_3, 0·0084 M NaOH. The principal conalbumin components migrate in the region 1–2 in. from the origin. The trailing border of ovalbumin (not shown) has migrated 6 in. from the origin. In the region 3–4 in. from the origin is seen an additional egg white polymorphism, described by Lush (ref. 3)

(*b*) Autoradiograph from gel of Fig. 1*a*. Radioactive iron is bound to only two of the three conalbumin components observed in the amido black stain. Only one (at 2·25 in. from the origin) of the three faint more rapidly migrating iron-binding components observed in this and other buffer systems is clearly seen; the second of these components has migrated 2·75 in. and the third 3·5 in. from the origin

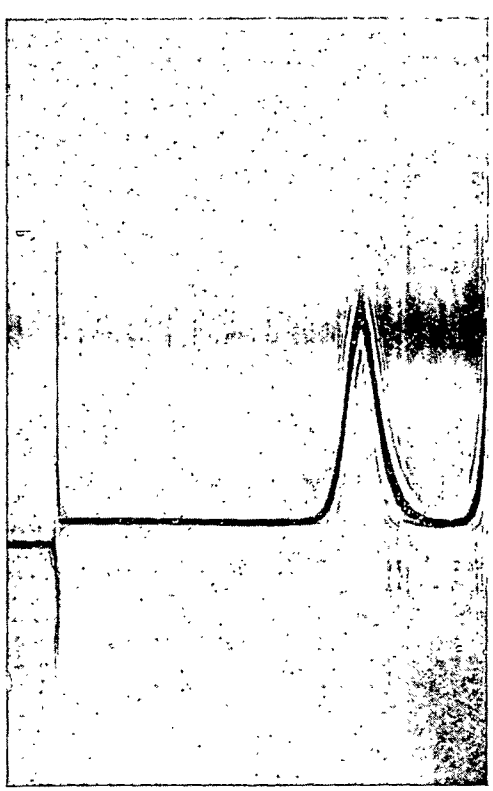

Fig. 2. Ultracentrifugal analysis of purified conalbumin in borate buffer. Protein concentration, 30 mg/ml.; solvent, 0·020 M H_3BO_3, 0·0084 M NaOH; *p*H 8·9; cell width, 3 mm; speed, 56,100 r.p.m.; time of photograph, 147 min; phase plate angle, 70° ; $s^{3\%}_{20^\circ,w} = 4{\cdot}55$

The eluted component also gave rise to faint, more rapidly migrating iron-binding components.

In a gel buffer of twice the usual concentration of boric acid and sodium hydroxide, and in buffers of the same boric acid concentration (0·020 M metaboric acid) but reduced sodium hydroxide concentration (0·0038 M, *p*H 8·57; 0·0010 M, *p*H 7·93), the proportions of the additional components were increased. However, the alterations induced in this fashion were less dramatic than those achieved by varying the conalbumin concentration. In all these experiments, the more concentrated borate buffer of Smithies[16] (0·30 M metaboric acid, 0·060 M sodium hydroxide; *p*H 8·2) was used in the electrode vessels. The three faint, more rapidly migrating components observed in the *tris*-citrate and phosphate–citrate buffers were also present in the borate buffers; no heterogeneity of these components could be detected in the boric acid system. In sedimentation velocity investigations in the ultracentrifuge (Fig. 2), a single slightly asymmetric peak was observed for purified conalbumin over the range of protein concentrations for which the boric acid effect was present in the starch gel.

The electrophoretic mobilities of the two prominent boric acid-induced components varied according to the concentration of the components. In an experiment in which egg white was diluted with isotonic saline in twelve steps to a final dilution of 1 : 8 (Fig. 3), the mobility of the slowest component gradually increased until it coincided with the intermediate component, the mobility of which also gradually increased until it coincided with the fast component. The mobility of the fast component remained constant throughout the experiment.

No definite explanation can be given for the effect of boric acid buffers on conalbumin. The concentration-dependent heterogeneity suggests the formation of complexes between boric acid and conalbumin which alter the electrophoretic mobility of the protein[19]. Boric acid complexes are well known in carbohydrate and nucleic acid chemistry[20], and a small carbohydrate moiety has been determined in conalbumin[4]. It is of interest that the postulated formation of the complex in the slowest migrating component appears to affect the capacity of the conalbumin molecule to bind iron. It is possible that the formation of the complex may also involve the carbohydrate of the gel supporting medium. The dilution and the elution experiments require that the formation of the complex be reversible, whether or not the starch gel is involved. The elution experiments also suggest that the faint, more rapidly migrating components observed in all buffer systems may represent an equilibrium with the principal conalbumin components. The sedimentation velocity experiments indicate that the effect cannot easily be attributed to aggregation of the protein. A similar phenomenon has not been observed for various concentrations of purified human transferrin or for transferrin in the serum of other animal species.

We thank Dr. David A. Yphantis for assistance in the ultracentrifugal analyses. This work was supported by a grant from the (U.S.) National Foundation.

Reduction and Reoxidation of the Disulphide Bonds of Pepsinogen

Anfinsen and Haber have shown that the disulphide bonds of ribonuclease (RNase) can be cleaved by treatment of the native protein in 8 M urea with mercaptoethanol[1]. On exposure to molecular oxygen, reduced RNase is re-oxidized with complete regeneration of secondary and tertiary structure. The kinetics of the reaction indicate either that pairing of the correct half-cystine residues is a random process with the molecule undergoing subsequent structural rearrangement to yield the native form[2]; or, alternatively, that the reduced protein may be sufficiently structurally similar to the native enzyme to allow correct matching and reoxidation of the half-cystinyl residues, even in the absence of the disulphide bridges[3].

We have made similar observations with the enzyme precursor, pepsinogen. In a typical experiment, 40 mg Worthington chromatographically pure pepsinogen (lot 6021) was dissolved in 2·5 ml. 8·0 M urea, 0·1 M potassium chloride, 0·01 M *tris* buffer, *p*H 8·5. To this solution, 0·1 ml. of redistilled β-mercaptoethanol (Eastman Organic) was added, the vessel was flushed with nitrogen, stoppered, and the solution heated in a 37° water bath for 3 h. The reduced protein was chromatographically separated from the reducing medium at 4° on a *G*-25 medium grade 'Sephadex' (Pharmacia Company, Uppsala, Sweden) column, 1·9 × 45 cm, by elution with 0·1 M potassium chloride, 0·02 M dipotassium hydrogen phosphate–potassium dihydrogen phosphate

buffer, *p*H 5·9. The major portion of the protein was eluted in the first column volume, and all work reported in this communication pertaining to reduction was conducted on a pooled eluate of the two most concentrated fractions.

The degree of reduction of the protein, which contains 3 disulphide bonds[4], was determined by titration at *p*H 7·0 of 3·0 ml. of a sample, approximately 20 μg/ml., with either 0·8 or 0·4 mM *p*-mercuriphenylsulphonate[5]. The amount of reacted mercuriphenylsulphonate was determined spectrophotometrically by observing the change in absorption at 240 mμ. Aliquots of the solution were assayed for peptic activity after activation for 10 min at *p*H 2·0 by the hæmoglobin substrate method[6]. The percentage recovered activity was calculated by a comparison with a pepsinogen sample in the same buffer system. Re-oxidation was accomplished by allowing the solution to stand at room temperature for 20–24 h at *p*H 8·4. (The recovery of activity of reduced pepsinogen varies linearly with *p*H. For example, within the *p*H-range of 7·0–8·5, aliquots containing 9·2 μg protein/ml. recovered 44–52 per cent of theoretical activity). Fig. 1 shows the results of the changes observed with peptic activity assay and the mercurial titration.

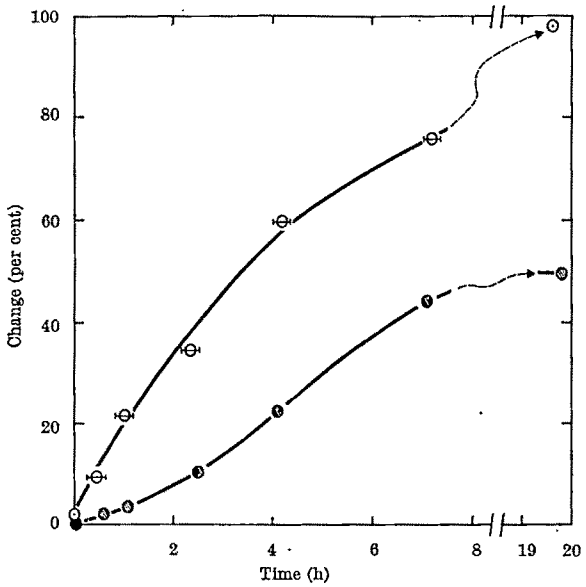

Fig. 1. Time-dependent changes in the SH groups and in the potential activity of reduced pepsinogen. Re-oxidation values are plotted as the midpoint of the time required for complete titration of a single sample. Zero time is that time when the *p*H value of the reduced protein solution was adjusted from 5·9 at 4° to 8·4° at room temperature. ○, Re-oxidation; ●, recovered activity

Three physico-chemical techniques, polarization of fluorescence[7], sedimentation, and viscosity, have been utilized for partially characterizing denatured pepsinogen and denatured-reduced pepsinogen as compared with the native protein.

Comparatively, RNase exhibits appreciable variation in ρ_h^{25} [2] between the native, denatured, and denatured-reduced states. ρ_h^{25} is defined as the mean relaxation time at 25° for a protein in a medium of known composition[7,8]. The respective values of ρ_h^{25} calculated for the foregoing states of pepsinogen as the 1-dimethylamino-naphthalene-5-sulphonyl conjugate are: $13{\cdot}0 \times 10^{-8}$, $1{\cdot}10 \times 10^{-8}$ and $0{\cdot}70 \times 10^{-8}$ sec (±20 per cent). Obviously, the protein undergoes a major loss of rigidity on denaturation; however, some secondary structure apparently persists after reduction in view of the finite value of ρ_h^{25}. Along with the 3 disulphide bonds, a phosphodiester linkage contributes to the secondary structure of the molecule, although the diester bond is not essential for potential enzymatic activity[9].

Changes in intrinsic viscosity also parallel those found with the polarization of fluorescence technique. Values of $[\eta]$ for the native and urea-denatured states of 3·7 and 28·7 ml./gm have been obtained at 27° using an Ubbelohde viscometer. The value for the reduced-denatured molecule is slightly higher than that cited for the denatured state. Urea-denatured pepsinogen used for the viscosity experiment here was dialysed for 24 h at 4° against 0·1 M potassium chloride, 0·02 M phosphate buffer, *p*H 7·0. When assayed by the hæmoglobin substrate method, practically all the theoretical activity was present.

Sedimentation diagrams of re-oxidized pepsinogen show a single boundary which has a sedimentation coefficient close to that of the native protein value, $3{\cdot}66 \times 10^{-13}$.

Both native and re-oxidized pepsinogen were subjected to starch-gel electrophoresis for 4 h at 4° using a 7·0 mM *tris*-citrate buffer, *p*H 8·4, with subsequent development of the gel slab by amido black dye. The former showed one well-defined zone with two minor components which migrated behind the major zone. Re-oxidized material gave the same major band with a broad ill-defined trailing region, the front of which moved at a rate intermediate to the two lesser components found in the native protein sample.

These experiments indicate that the tertiary and most of the secondary structure of pepsinogen can be disrupted without greatly affecting the ability of the polypeptide chain to recover some of its structure and, possibly as a consequence, some of its activity. At present, however, it would be premature to assert that the recovered active molecule is identical in all respects to native pepsinogen.

Nitrogenous Components of Phospholipids extracted from *Penicillium chrysogenum*

Previous work carried out on the lipids of *Penicillium chrysogenum*[1,2] has implicated the phospholipids as important metabolic constituents of the mould. Subsequent analysis of these phospholipids on silicic acid impregnated paper indicated the presence of a number of compounds having R_F values similar to those obtained by Marinetti *et al.*[3] for phospholipids isolated from rat liver and heart tissue. Silberman and Gaby[4] have identified the majority of nitrogenous compounds present in the aqueous fraction of the acid hydrolysate of phospholipids extracted from the Gram-negative bacillus *Pseudomonas aeruginosa* by two-dimensional chromatography as choline, leucine, valine or methionine, ethanolamine, alanine, threonine, lysine, glycine, glutamic acid, serine, cysteine and aspartic acid.

In more recent investigations it was of interest to find that these nitrogenous compounds were also present in

Table 1. Nitrogenous Compounds present in the Phospholipid Hydrolysates of Silicic Acid Column Fractions identified by Paper Chromatography

the acetone insoluble phospholipid fraction extracted from *Penicillium chrysogenum*, Ehrlich ascites cells and normal rabbit liver cells. The types and amounts of nitrogenous compounds present in the cellular phospholipids could be increased by the addition of specific amino-acids to the actively metabolizing cells[4]. While it is well known that amino-acids and other non-lipid compounds appear to follow phospholipids during fractionation procedures recent evidence would seem conclusively to establish the fact that these nitrogenous compounds are metabolic complexes and are firmly bound to the phospholipid or phospholipid-like compounds[4–9]. An attempt was made, therefore, to identify the nitrogenous compounds associated with the phospholipid fractions of the mould *P. chrysogenum* by analysing the aqueous acid hydrolysates of the acetone insoluble lipids with the aid of a Technicon autoanalyser.

The mould *P. chrysogenum*, strain 47-133*SL*5, was grown in the 3 per cent cornsteep, 3 per cent lactose, 1 per cent calcium carbonate medium previously described[1]. The lipid fraction was extracted from the washed filtered cells with a chloroform–methanol (50 : 50 v/v) mixture for 24 h at 100° in a Soxhlet extraction apparatus or by extracting the mould cells at room temperature (25°) on a rotary shaking machine for 48 h using the same chloroform–methanol solvent mixture. No significant differences in yield of phospholipids was observed when the two procedures were compared.

The chloroform–methanol extract was evaporated to dryness under vacuum and the residue extracted with petroleum ether. The petroleum ether soluble material was concentrated under partial vacuum to approximately 10 ml., and the phospholipids precipitated in 150 ml. acetone. The phospholipids were further purified by redissolving the precipitate in 10 ml. petroleum ether, washing the ether soluble phospholipids with several changes of distilled water and 0·9 per cent saline (100 ml. vol.) and reprecipitating in 150 ml. acetone. This procedure was repeated 3–5 times. The final wash contained no ninhydrin positive compounds as determined by paper chromatography. A 30–50 mg sample of the acetone insoluble lipid was hydrolysed by refluxing in 6 N hydrochloric acid for 24 h at 100°. A part of the aqueous hydrolysate (equivalent to 15 mg lipid) was placed on a 150-cm column of 'Amberlite *IR*-120' (average particle diameter of 56μ) and subjected to analysis by the automatic amino-acid analysis technique of Moore *et al.*[10]. Approximately, 50 mg of the acetone insoluble lipid in 5-ml. chloroform was placed on 10 × 455 mm columns containing 20 g silicic acid ('Unisil') and fractions eluted from the columns with 200-ml. amounts of each of the following solvents: chloroform, chloroform–methanol 80–20 v/v, 20–80 v/v, and absolute methanol in the order given. A total of 20 fractions were collected each containing 50 ml. Each fraction was concentrated under vacuum and 30 μl. or more (depending on concentration) were spotted on silicic acid impregnated paper, developed with diisobutyl ketone-acetic acid-water, and the rhodamine G, ninhydrin and choline positive areas determined[4]. The remaining portion of the fractions was hydrolysed by refluxing in 6 N hydrochloric acid for 24 h and the water-soluble nitrogenous compounds identified by two-dimensional paper chromatography.

Total recovery of the lipids eluted from silicic acid columns was 95–98 per cent. Approximately 45–55 per cent of the total weight was recovered in the 80/20 chloroform–methanol solvent fraction, 25–30 per cent recovered in the 60/40 and 10–15 per cent recovered in the 20/80 fractions. Most of the phospholipids appeared in the first 50-ml. fraction of each solvent mixture collected from the column. If the resting mould cells were incubated with an amino-acid labelled with carbon-14, that is, DL-lysine-1-^{14}C, prior to lipid extraction, the peak of specific radioactivity was eluted from the column in the first 50 ml. of the 60/40 chloroform–methanol solvent mixture. If the chloroform–methanol mixtures passed through the column were varied by 10 per cent increments, that is, 90/10, 80/20, etc., the peak of specific radioactivity appeared in the 70/30 fraction.

Each of the solvent fractions, following acid hydrolysis, was chromatographed in two dimensions on Whatman No. 1 filter paper at room temperature (25°) by the ascending technique using *n*-butanol–acetic acid–water (50 : 12 : 50 v/v/v) as the first solvent and phenol–water (80 : 20 v/v) as the second solvent. Known compounds were run separately and mixed with the hydrolysates to identify unknown spots. Identification was confirmed by repeated chromatograms substituting pyridine–acetic acid–water (50 : 35 : 15 v/v/v) for one of the original solvent mixtures. Table 1 lists the water-soluble nitrogenous compounds identified in the first 50-ml. fraction of each solvent or solvent mixture. Serine, glycine and glutamic acid were present in all of the fractions, including the chloroform fraction. Ethanolamine was the major compound present in the 80/20 fraction. Choline was detected in both the 60/40 and 20/80 chloroform–methanol solvent fractions. It is of interest to note that while the bulk of material was eluted in the 80/20 fraction the greatest number of nitrogenous compounds were eluted in the more polar solvent fractions. While it was possible to identify as many as 12 ninhydrin-positive compounds by paper chromatography it is obvious from the results presented in Table 2 that a more sensitive procedure, such as that described by Moore *et al.*[10], is required to demonstrate compounds present in minute quantities. The figures presented in Table 2 represent the averages of analysis of phospholipids obtained from three different cell preparations. The concentrations (μM) of most of the compounds varied with different cell preparations, that is, arginine varied from trace amounts to 2·0 M per 100 mg phospholipid. The percentage of each compound, however, remained remarkably constant. Duplicate analysis of each hydrolysate gave essentially identical results.

Macfarlane's[9] recent description of an acetone insoluble *O*-alanyl ester of phosphatidyl glycerol isolated from the Gram-positive bacillus *Cl. welchii* emphasizes the complexity of these compounds and supports the hypothesis that these complexes are important metabolic constituents of the cell.

Peroxidase Isozymes in Root Nodules of Various Leguminous Plants

Multiple forms of various enzymes (isozymes) have been shown in tissues of animals[1–3] and plants[4,5] and in micro-organisms[6]. The difference in electrophoretic mobility of some isozymes obtained from different species has been reported[4,5,7]. This communication reports the existence of peroxidase isozymes which differ electrophoretically in root nodules of each of four leguminous plants. The leghæmoglobins extracted from these different nodules also differ electrophoretically.

Plants of *Galega officinalis*, *Lotus pedunculatus*, *Trifolium repens* and *Vicia sativa* were grown from seed in sterilized sand which had been inoculated with the appropriate *Rhizobia*. Nodules were collected six weeks after planting and were kept at 3° until extracted within 3 h of collecting.

Extracts were prepared by grinding 8 g of nodules in a chilled mortar with 8 ml. of 0·05 M *tris* hydrochloric acid buffer at *p*H 7·5. This method of extraction does not disrupt the *Rhizobia* which inhabit the nodules[8]. The slurry was centrifuged at 20,000*g* for 20 min and the supernatant was fractionated with ammonium sulphate at 3°. The protein precipitated between 55 and 80 per cent saturation ammonium sulphate was dissolved in 3 ml. of 0·05 M *tris* hydrochloric acid buffer at *p*H 7·5 and dialysed against 200 ml. of the same buffer at 3° for 18 h.

Starch-gel electrophoresis was carried out as described by Smithies[9] in 0·05 M *tris*-citrate buffer *p*H 8·6. After completion of the run the gel was sliced horizontally in two. One half was stained by amido black to reveal protein bands and the other half was stained to reveal the peroxidase bands by immersing it in a solution containing 0·025 per cent benzidine, 1 per cent hydrogen peroxide and 5 per cent acetic acid in 50 per cent aqueous ethanol. The parts of the starch gel containing peroxidases showed a blue coloration. Leghæmoglobins, which could be identified as brown bands prior to staining, gave the peroxidase reaction when stained with the benzidine reagent.

In both Figs. 1 and 2 leghæmoglobins are marked by the letters *A* and *B*. It will be seen that the two leghæmoglobins in the nodules of the four plants vary in electrophoretic mobility. The slowest moving bands are those of *Trifolium repens* and *Galega officinalis* followed by those of *Vicia sativa* and *Lotus pedunculatus*. The

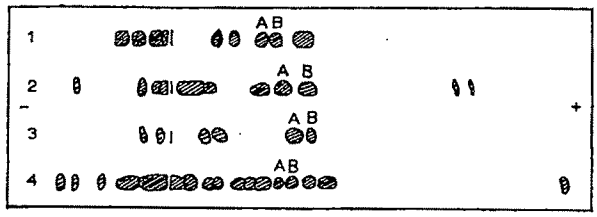

Fig. 1. Electrophoretic pattern of peroxidases in root nodule extracts. 1, *Trifolium repens*; 2, *Vicia sativa*; 3, *Lotus pedunculatus*; 4, *Galega officinalis*

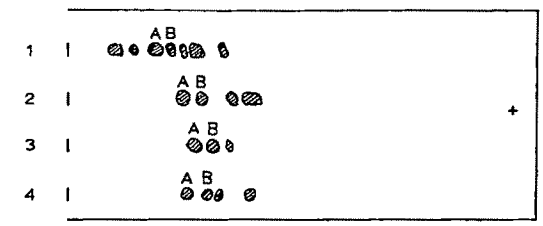

Fig. 2. Electrophoretic pattern of proteins in root nodule extracts. 1, *Trifolium repens*; 2, *Vicia sativa*; 3, *Lotus pedunculatus*; 4, *Galega officinalis*

difference in electrophoretic mobilities between leghæmoglobins of root nodules of different plant genera has a counterpart in animal kingdom, where there are differences between electrophoretic mobilities of hæmoglobins of various species of vertebrates[10].

The zymograms of peroxidases in root nodules (Fig. 1) show a characteristic pattern for each of the plants used in this work. The most outstanding differences between the peroxidase patterns are the fast sharp bands moving towards the anode in nodule extracts of both *Galega officinalis* and *Vicia sativa* which are not present in extracts of nodules of the other two plants. Although most of the peroxidase bands showed intense enzymatic reaction they did not contain enough protein to stain with amido black. In the gels that were stained with amido black no bands were observed on the cathode side of the origin (Fig. 2).

The specific role of each of the peroxidase isozymes in root nodules and the biological significance of the difference in the peroxidase pattern in nodules of different leguminous plants remain to be established.

PHYSIOLOGY

Storage of Insecticides in French People

Storage of DDT in people without occupational exposure to the compound reflects their dietary intake[1]. Measurement of storage in a random sample of the population of the country may be used as an index of residues of other pesticides as well as those of DDT in the total food supply. We were fortunate in obtaining samples of adipose tissue from ten French people. Even though the number is small, the results are of interest because they are the first from France and because they permit a comparison with results from other countries.

* Values based on original data.

The adipose tissue was taken at autopsy from people of widely different ages and occupations, but without occupational exposure to DDT. The causes of death are listed in Table 1, but in no instance was DDT involved. The tissue was weighed before being placed in 10 per cent formaldehyde (4 per cent formalin solution) for preservation during shipment. Earlier investigation has shown that this method of preservation is satisfactory for such samples[1].

Suitable portions of the samples were ground in a mortar with sodium sulphate. The ground tissue was then transferred to 500 ml. glass-stoppered bottles with the aid of carbon tetrachloride. Approximately 200 ml. of carbon tetrachloride were added to each bottle and the bottles were then mechanically shaken for 2 h. The samples were then filtered and the filtrate analysed for DDT and DDE by the Schechter–Haller method as modified by Mattson *et al.*[2]. In view of the weight of the available samples, the smallest concentration of DDT which could be detected by this method was 0·8 p.p.m.

Five of the samples—Nos. 2, 4, 6, 7 and 8—gave Schechter–Haller positive results and were large enough to permit further examination using gas chromatography. The remaining portion of each sample was extracted as described and the extract passed through a Davidow[3] column as a clean-up procedure. The carbon tetrachloride eluates were evaporated to complete dryness in test tubes in a 75° C water bath with the aid of a gentle stream of air. The tubes were then rinsed down several times with *n*-hexane and the hexane evaporated off after each rinsing to rid the samples of carbon tetrachloride. The residues were finally taken up in *n*-hexane and 100 μl. (equivalent to about 3·5 g of fat) were subjected to microcoulometric gas chromatography described by Coulson *et al.*[4]. An aluminium tube (6 ft. × 0·25 in. outer diam.) packed with 30/60 mesh acid-washed 'Chromosorb-*B*' containing 20 per cent by weight of high vacuum silicone grease was used as the partitioning column. The column temperature was maintained at 215° C and the nitrogen carrier gas was maintained at 60 c.c./min. The effluent gases were oxidatively decomposed at 800° C and titrated coulometrically. Use of the Davidow column was necessary in a search for possible metabolites of DDT about which there is current interest. Unfortunately, dieldrin cannot be eluted from this column, so any dieldrin that may have been present could not be measured and the small size of the original samples precluded other investigations.

Results obtained by the colorimetric method are shown in Table 1. It may be seen that no DDT-related material was detected in 4 of the samples. The highest concentration of DDT found in the tissue of any person was 4·0 p.p.m. and the highest concentration of DDT plus DDE expressed as DDT-equivalent was 16·4 p.p.m. The average concentration of DDT in all samples was 1·7 p.p.m. and the average concentration for DDT plus DDE as DDT-equivalent was 5·2 p.p.m. Of course, the averages were higher if only the positive values were considered.

In samples showing detectable DDT, DDE constituted 56–75 per cent, or an average of 66 per cent of the total. This proportion is similar to that found in other studies of general populations[1].

Results obtained by gas chromatography are shown in Fig. 1. Curve *A* represents standard lindane, aldrin, and the *p,p'*-isomers of DDE, DDD, and DDT appearing in that order. Curve *B*, from sample No. 8, is representative of the various peaks found in the fat of the general population of France. The first peak appeared in all French fat and is indicative of lindane. Calculated as lindane the concentration ranged from 0·66 to 1·64 p.p.m. with an average of 1·19 p.p.m. The second peak (2*b*) appeared in 4 of the 5 fat samples examined; it represents an unknown compound distinct from aldrin (2*a*). Since the unknown compound passed through a Davidow column, it would appear to be a neutral material stable to strong acids. The third peak appeared in all French fats subjected to gas chromatography and is undoubtedly *p,p'*-DDE. The DDE concentration ranged from 4·2 to 7·1 p.p.m. with an average value of 4·8 p.p.m. This value was 19 per cent

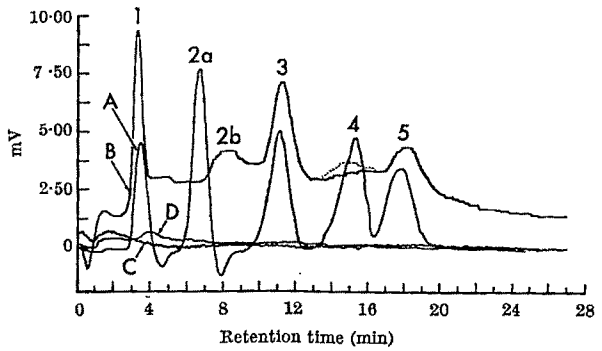

Fig. 1. Chromatograms resulting from gas-liquid separation and microcoulometric analysis of: (*A*) reference standards of (1) lindane, (2*a*) aldrin, (3) *p,p'*-DDE, (4) *p,p'*-DDD, and (5) *p,p'*-DDT; (*B*) sample No. 8 of fat from French people; (*C*) sample of fat from an American who died before 1942; and (*D*) Davidow column blank

lower than the average obtained for these same samples by the Schechter–Haller method. This difference may depend in part on the fact that these values were obtained from separate portions of the original samples. The fourth peak did not appear in the sample represented in Fig. 1, but its form is shown by a dotted insert. The fourth peak did appear in three of the fats and could be either *o,p'*-DDT or *p,p'*-DDD, or both, since standards of these two materials could not be resolved. The presence of *o,p'*-DDT in the fat would be expected, since the general population was most likely exposed to the technical form of DDT, which contains 20–25 per cent of the *o,p'*-DDT isomer. There is also the possibility that they could have been exposed to small amounts of *p,p'*-DDD and that it was stored as such in the fat. Another possibility, as will be reported elsewhere, is that *p,p'*-DDD could have been present as a metabolite of *p,p'*-DDT. The fifth peak appearing in fat was *p,p'*-DDT and was present in all samples subjected to gas chromatography. The DDT concentrations ranged from 2·3 to 5·0 p.p.m. with an average of 5·5 p.p.m., which was only 6 per cent higher than the average values obtained by the Schechter–Haller method for other portions of these same samples.

One human fat sample from the United States predating the introduction of DDT or lindane was also subjected to gas chromatography and appears as curve *C* in Fig. 1. No peaks were obtained with this fat; therefore, the compounds producing peaks in the fat of the general population were not natural constituents of fat but rather were present as a result of exposure to halogenated compounds. A Davidow column blank represented by curve *D* gave no peaks.

Table 2 permits a comparison of the results recorded here with the results of studies in other countries. Storage-levels for DDT in the general population are lower in Europe than in North America. This difference is almost certainly related to the amount of DDT used in agriculture in the different countries. It is recognized that any given crop planted in relatively small areas among other crops, in the manner generally used in Europe, is less susceptible to insect attack than is the same crop planted in extensive areas, as is frequently done in North America. Also, it seems likely that the climate of northern Europe is less conducive to insects than the climate of much of the United States.

Even though 4 of the samples contained no detectable DDT, the average concentration in the French samples was higher than that reported for West Germany or England. The results for the French samples are somewhat like those for United States samples in 1950 (ref. 5), although the range of values is smaller. It appears possible that the use of DDT in France is localized (either to certain crops or areas) in such a way that some people receive the compound in their diet while others get little or none.

In no country yet investigated do people without occupational exposure absorb as much DDT as do people who apply or formulate the compound.

Formation of Extra Nerve-muscle Junctions in Innervated Muscle

If a foreign motor nerve is connected to a normally innervated muscle, the nerve fibres grow into it but do not establish intimate contact with muscle fibres, and are unable to transmit impulses to them. On the other hand, if the muscle fibres are deprived of their normal innervation a foreign nerve will establish functional connexions with them[1–3].

Since any part of a nerve-free muscle fibre is capable of being innervated[3–5] the observations indicate that established nerve endings exert an inhibitory influence which ronders the whole muscle fibre incapable of accepting further innervation. As Harrison[6] pointed out in 1910, there is a certain analogy between a muscle fibre and an egg cell which once it is fertilized does not accept further spermatozoa.

In the experiments recorded here the tibial nerve of the frog was dissected in the leg and reflected up to the knee. It was then attached to the sartorius muscle, leaving its existing innervation intact. The site of attachment was very near the tibial end of the muscle fibres: that is, several mm away from the nearest myoneural junctions.

It was found that connecting the nerve to a muscle, the tibial end of which has been cut at the same time, leads to formation of accessory neuromuscular junctions in this region of the muscle fibres. A few months after the operation most muscle fibres have become innervated by the foreign nerve, and many of them respond with a propagated action potential and contraction to stimulation of the nerve.

For example, Fig. 1*A* shows an intracellular action potential evoked by stimulation of the tibial nerve, some 2 months after connecting it to a cut sartorius muscle; Fig. 1*B* illustrates the action potential elicited in the same muscle fibre through stimulation of the original sartorius nerve. The larger stimulus-response delay in *A* is due partly to propagation time in the muscle fibre itself and partly to slower conduction in the regenerated nerve fibres[7].

Spontaneous sub-threshold potentials similar to those which occur at normal neuromuscular junctions[8] could be recorded from the muscle fibre if the microelectrode were inserted near the site of nerve implant. Furthermore, these regions also develop the accumulation of cholinesterase characteristic of normal end-plates.

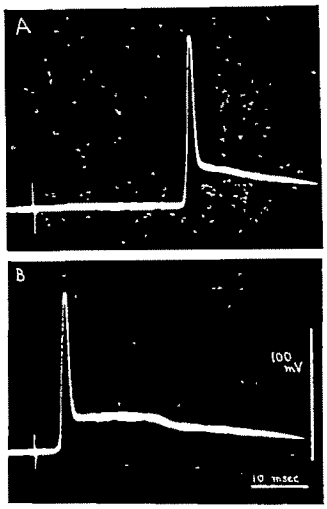

Fig. 1. Induced extra innervation in a frog's sartorius muscle fibre, 63 days after transection of the muscle and implantation of a foreign nerve (tibial) near its lower end. *A*, Intracellular action potential evoked by stimulation of the tibial nerve. *B*, action potential, recorded in the same place of the muscle fibre, after stimulation of the sartorius nerve. The recording electrode was near an original end-plate. Resting potential, 92 mV

Thus the 'barrier' which causes muscle fibres to reject additional innervation can be overcome experimentally by local injury to the muscle fibres. Under these conditions, muscle fibres will accept innervation by other motor nerves even in the presence of the original functioning myoneural synapses. It is of interest that local injury of muscle fibres has previously been found to overcome the inhibitory neural influence which reduces acetylcholine sensitivity along most of the muscle fibre[9]. It is possible that a similar procedure may help to establish experimentally new interneuronal connexions.

In vitro Effect of Lowering Surface Energy on Esterase Activity of *Musca* Homogenates

The primary reaction between an enzyme and a substrate or a poison is essentially an adsorption reaction involving the concentration of the substance in the enzyme/water interface. Homogenates are bio-colloids where the surface energy, particularly at interfaces, is a predominating form of energy on changes of which depend certain phenomena. In aqueous preparations of enzymes, substances which lower surface energy by concentrating at the enzyme/water interface may behave as barrier between enzyme and substrate, unless the latter has a higher affinity for interfaces.

Some surface active agents have been tested for their effect on the activity of cholinesterase from *Musca* heads, using acetylcholine as substrate at the optimum concentration of $1{\cdot}5 \times 10^{-2}$ M at 37° C. Sodium cholate caused full inhibition at a concentration of 0·2 M. Sodium lauryl sulphate was extremely potent and inhibited enzyme activity completely at $2{\cdot}5 \times 10^{-4}$ M. No practical method is known by which tension at the enzyme/liquid interface can be determined, and measurements of surface tension of solutions containing these compounds at various concentrations only served to show the relation between levels of inhibition and changes in surface tension. At the foregoing concentrations, surface tension values were 49·5 and 32·5 respectively, as compared with that of water of 70·4 dynes/cm at 37° C. With each compound, the level of inhibition was greater at the concentration which gave lower surface tension value. Similar results were obtained with the aliesterase from the thorax using, in addition, sodium oleate, which gave full inhibition at 5×10^{-3} M.

N-butanol is known to activate acetyl-cholinesterase of *Musca*, possibly through activating a pro-enzyme[1]. On the other hand, it makes homogenates resistant to some degree to OP insecticides. Iso-OMPA and TEPP inhibit esterase activity at $0{\cdot}4 \times 10^{-4}$ and 10^{-3} M respectively. However, at 0·9, 1·8, 2·7, 3·6 and 4·5 per cent butanol, the levels of inhibition by these compounds are 100, 100, 73, 37 and zero per cent for iso-OMPA and 100, 100, 100, 73 and 45 per cent for TEPP. Residue analysis showed that the amount of iso-OMPA which formed salt with proteins was less in butanol-treated than in control homogenates. These results again may be explained if we take into account the effect of butanol on lowering the surface tension of water. Surface tension values at the above concentrations of the alcohol were 60, 52, 46·5, 36·5 and 29·6 dynes/cm respectively, and it follows from Gibbs's equation $C_2 = -\frac{C}{RT}\frac{d\gamma}{dC}$ that adsorption is greatest from solvents which have a high surface tension due to the fact that a greater change $d\gamma/dC$ can be brought about in a dispersions medium having a high surface tension than from one having a low surface tension value.

The toxicity of OP compounds and possibly others must be dependent in the first place on a very complex set of physico-chemical factors which determine the rate of uptake of these compounds by colloidal particles from the dispersions medium of the cytoplasm. In addition to the nature and concentration of the insecticide,' surface energy changes may be one such factor. A second factor is the degree of hydration of protein micelles. Loss of the liquid of solvation in presence of large amounts of electrolytes may, in some cases, facilitate a chemical reaction between enzyme and insecticide. For example, enzyme incubated with iso-OMPA in presence of 1 M NaCl was fully inhibited at half the dose necessary to bring about full inhibition when incubation was made in distilled water. Similar results were obtained when homogenates were flocculated with ammonium sulphate at 25 per cent saturation.

Quantitative Aspects of Pinocytosis in Relation to Intestinal Absorption

One hypothesis to account for the way in which fat is taken up by the cells of the intestinal mucosa of mammals is that the cells engulf droplets of fat by the process of pinocytosis[1-4]. The quantitative aspects of the phenomenon of pinocytosis are of interest for the reason that the size of the vesicles that have been described in this connexion are so small that in order to engulf physiological quantities of fat the number required and the rate at which they are formed must be correspondingly large. In Table 1 are given the numbers of spherical vesicles of differing radii, of the order of size described for pinocytotic vesicles in rat intestine, that are required to be formed to engulf a volume of 1 ml. The total surface of the vesicles is also shown.

An albino laboratory rat of about 300 g body-weight will consume some 0·5–1·0 g fat per diem. Working on the basis that the absorption occurs over a period of 10 h in the upper third of the small intestine, the rate of formation of pinocytotic vesicles necessary to achieve the total absorption of the dietary fat in particulate form may be calculated. From the results of Fisher and Parsons[5], the surface area of the mucosa of the upper third of the small intestine of a 300-g rat is 150 cm^2. This figure refers to the area presented by the mucosal cells to the intestinal lumen and does not take into account any effects produced by the presence of the microvilli. If the projected area of the mucosal face of an intestinal epithelial cell of the rat is 15μ^2, the total number of absorbing cells in the upper third of the small intestine of the rat is thus 10^9. These data are used to show in Table 1 the total number of vesicles required to be formed by each intestinal mucosal cell for a volume of 1 ml. to be taken up by the absorbing surface. The rate of formation of vesicles, $cell^{-1}$ sec^{-1}, which is necessary for a total volume of 1 ml. to be engulfed is also shown. Measurements which are given by Palay and Karlin[1] indicate that the diameter of the vesicles found in the region immediately below the microvilli of the mucosal cells of the fat-absorbing rat intestine is of the order of 60 mμ. It then follows that the rate of pinocytosis necessary for 1 ml. of dietary fat to be absorbed over a period of 10 h is 250 $cell^{-1}$ sec^{-1}. Each intestinal mucosal cell appears to possess about 500 microvilli, so that with vesicles 60 mμ in diameter this rate of vesiculation is equivalent to the formation of one pinocytotic vesicle in the bordering membrane of each intermicrovillus space every 2 sec throughout the 10-h absorption period.

Table 1

Radius of vesicle (mμ)	No. of vesicles to contain 1 ml.	Vesicular surface per ml. content (cm^2)	For absorbing surface containing 10^9 cells, and for 1 ml., to be absorbed over 10 h: Total No. of vesicles to be formed by each cell	For absorbing surface containing 10^9 cells, and for 1 ml., to be absorbed over 10 h: No. of vesicles to be formed per cell per sec
5	$1·8 \times 10^{18}$	$6·0 \times 10^6$	$1·8 \times 10^9$	50,000
10	$2·4 \times 10^{17}$	$3·0 \times 10^6$	$2·4 \times 10^8$	6,700
25	$1·5 \times 10^{16}$	$1·2 \times 10^6$	$1·5 \times 10^7$	420
30	$9·1 \times 10^{15}$	$1·8 \times 10^6$	$9·1 \times 10^6$	250
50	$1·8 \times 10^{15}$	$6·0 \times 10^5$	$1·8 \times 10^6$	50
100	$2·4 \times 10^{14}$	$3·0 \times 10^5$	$2·4 \times 10^5$	7
200	$2·9 \times 10^{13}$	$1·5 \times 10^5$	$2·9 \times 10^4$	0·8

For human intestine, with 100 ml. fat absorbed over a 10-h period by the upper third of the small intestine, a similar calculation based on an estimated absorbing surface of $3·3 \times 10^4$ cm^2 (see, for example, Wilson[4]) and therefore containing 2×10^{11} absorbing cells yields an estimate of $4·5 \times 10^6$ vesicles of 60-mμ diameter to be formed per cell during the absorption period. This is equivalent to the formation of 150 $cell^{-1}$ sec^{-1} throughout the 10-h absorption period, a rate of vesiculation which is very similar to that calculated for the rat.

It is to be noticed that, for a diameter of 60 mμ, the projected area of one vesicle is 3×10^{-11} cm^2. Now with the projected area of the mucosal face of an absorbing cell as 15×10^{-8} cm^2, the area of this face which is occupied by the feet of 500 microvilli of 0·1μ diameter is $3·75 \times 10^{-8}$ cm^2, so that the remaining area which would be available for the formation of vesicles is about 10^{-7} cm^2. This area is equal to the projected area of more than 3,000 vesicles of 60-mμ diameter. In other words, there appears to be sufficient space in the cell membrane around the bases of the microvilli to accommodate the simultaneous formation of more than 3,000 pinocytotic vesicles of diameter 60 mμ.

These calculations will be in error in so much as the estimates of the parameters of the absorbing mucosal surface may be in error. The calculations are also based on the assumption that the dietary fat is converted with only trivial changes in volume by the processes of digestion into a form which is subjected to pinocytosis. If, in fact, only a fraction of the dietary fat is assimilated by pinocytosis by the mucosal cells, the rest being absorbed in some other form, then the estimates given in Table 1 will be too high. On the other hand, the calculations take no account of the presence of goblet cells in the intestinal mucosal cellular population. If these cells do not assimilate fat by pinocytosis, then the estimates given in Table 1 are somewhat too low.

Higher rates of vesiculation are required if pinocytosis is to represent a major channel for the reabsorption of other substances, for example, the digestive secretions. Thus in the case of an adult human subject, with the digestive secretions totalling 7 litres per day[6], the reabsorption of this volume of fluid entirely by pinocytotic vesiculation undertaken by all the cells of the whole small intestine would require a rate of vesicle formation of the order of 1,000 $cell^{-1}$ sec^{-1} for the whole 24 h, the vesicles having a mean diameter of 60 mμ.

Since the work done in forming a new area of surface in opposition to the interfacial tension is T ergs cm^{-2}, where T is the interfacial tension in dynes cm^{-1}, the work that has to be done by the cells in forming the surface of the vesicles appears to be very small. The data for the vesicular surface, which are given in Table 1, are numerically equal to the work done in ergs in forming the surface of vesicles of the dimensions given and with an interfacial tension of 1 dyne cm^{-1}.

Thus the absorption of 100 ml. fluid by pinocytotic vesicles of 30 mμ radius would require the expenditure of about 2 g calorie per dyne cm^{-1} of interfacial tension in the wall of the vesicles. However, the existence of an interfacial tension of 1 dyne cm^{-1} in the wall of a pinocytotic vesicle of radius 30 mμ requires that, in order to balance the force due to the tension, the intravesicular pressure should exceed the external pressure by about 200 mm mercury. On the other hand, if the pressure differential existing across the walls of vesicles of that size is as low as, say, 2 mm mercury, the interfacial tension must be 1/100 dyne cm^{-1}, and the work done in forming the new area of surface contained in the vesicles will be correspondingly smaller.

Effect of Different Vasomotor Agents on the Visco-elastic Behaviour of Arteries of the Muscular Type

It has been assumed that two different contractile systems are present in the vascular muscle: the phasic system for transient regulatory tension and the tonic system for continuous tension. The tension of the latter seems to depend on the concentration of potassium in the muscular cells[1]. This opinion has been confirmed during physiological and biochemical investigations[2–4].

The work recorded here presents further evidence in favour of this theory by the observation of the visco-elastic behaviour of blood vessels of the muscular type. The method of quick-releases has been used[5].

Rectangular strips of the carotid from a cow, immersed in Tyrode's solution at body-temperature, are slowly and progressively stretched perpendicularly to the anatomic axis of the vessel. When a chosen tension has been reached stimulation is caused, in isometric conditions, by different vasomotor agents (potassium chloride 75–95 mM; cæsium

chloride 25–30 mM; barium chloride 5 mM; adrenaline 0·5 γ/c.c.; histamine 15–20 γ/c.c.; hypertensin 0·1 γ/c.c.; electricity 14 V, 50 cycles/sec). At maximal tension, the artery strips are allowed to shorten suddenly to various degrees (Δl = 0·75–5 per cent of the initial length). The variations of tension (ΔT) are recorded by means of an electronic transducer R.C.A. 5734 (ref. 6).

The modulus of elasticity (Young's modulus) is defined by the equation (1):

$$E = \frac{\Delta T}{\Delta l} \times \frac{\text{length}}{\text{transverse section}} \qquad (1)$$

The results of our experiments may be summarized as follows:

(1) The modulus of elasticity is not constant but rises parallel to tension (Figs. 1*A* and *B*). The relation observed between these two variables suggests an equation of the following type[7]:

$$P_2 = P_1 \times e^{-\Delta l/\lambda}$$

where P_2 is the tension after quick release; P_1 is the initial tension: λ a constant of length.

Accordingly, when Δl is plotted against log P_1/P_2, a straight line is obtained (Figs. 2 and 3).

(2) The different vasomotor agents may be grouped into two different categories:

(*a*) The first one contains potassium, cæsium and barium chlorides and histamine. The variations of the modulus of elasticity during the contraction produced by these substances are exactly equal to those measured during the rise of tension obtained by a passive elongation of the artery at rest (Figs. 1*A* and 2).

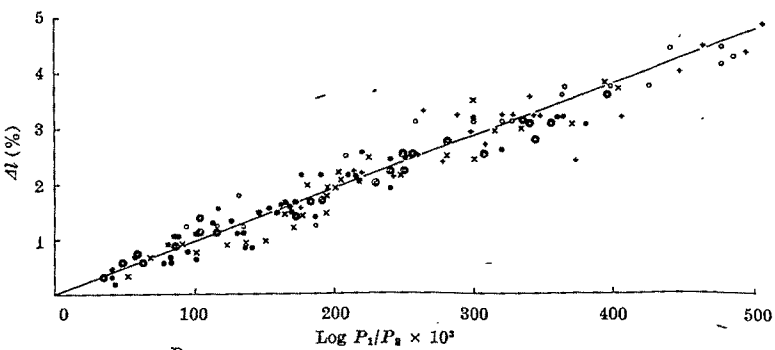

Fig. 2. Log $\frac{P_1}{P_2} \times 10^3$ versus the variations of length, Δl, expressed as a percentage of the initial length; arteries excited by potassium chloride (+ and ×), cæsium chloride (●), barium chloride (○) and histamine (⊙). Artery at rest, *. λ = 4·15 cm per cent

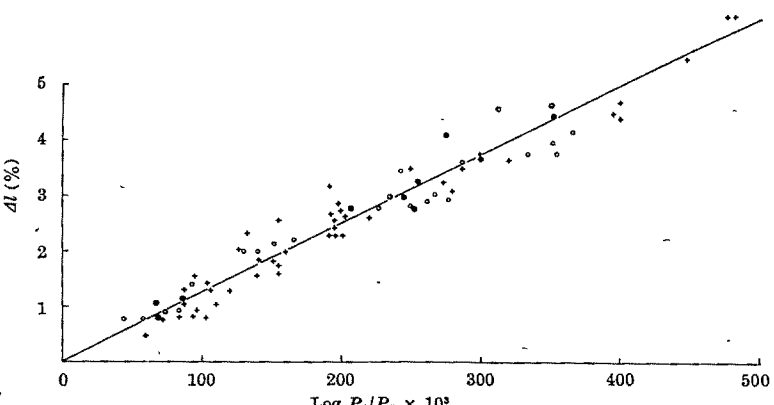

Fig. 3. Log $\frac{P_1}{P_2} \times 10^3$ versus the variations of length, Δl, expressed as a percentage of the initial length; arteries excited by adrenaline (●), electricity (○) and hypertensin (+). λ = 5·80 cm per cent

(*b*) Electricity, adrenaline and hypertensin form the second group. The contraction by these agents is accompanied by variations of the modulus of elasticity which are smaller than those observed when the substances of the first group are used (Figs. 1*B* and 3). Thus, the artery contracted by adrenaline seems to be more extensible than an artery stimulated by potassium chloride.

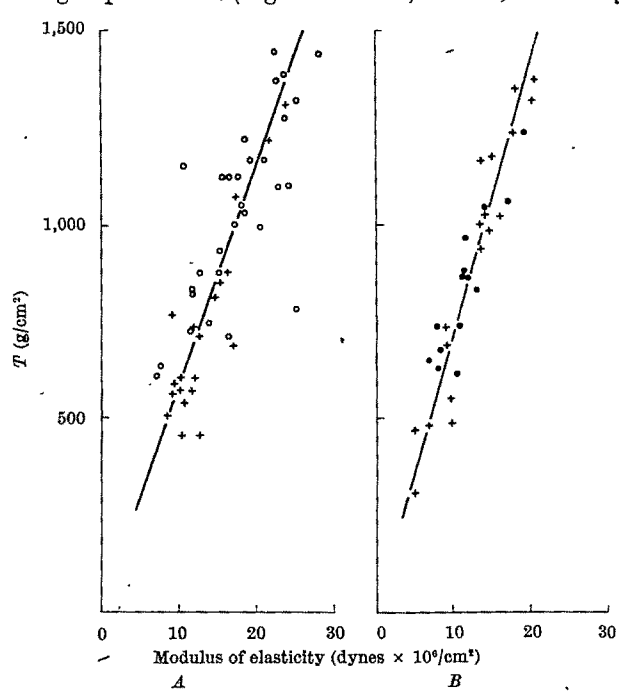

Fig. 1. Plots of Young's modulus against tension. *A*, Artery at rest (+) or excited by potassium chloride (○); *B*, artery excited by adrenaline (●) or electricity (+)

New investigations using other experimental methods give a superposable classification of these vasomotor agents. These results show that each group of substances act on a different contractile system and confirm Laszt's hypothesis[8].

PHARMACOLOGY

Effects of Lysergic Acid Diethylamide on the Total Leukocytes and Eosinophils of the Female Rat

The hallucinogenic drug, lysergic acid diethylamide (LSD-25), produces in minute doses marked aberrations in mental functions. The psychic symptoms of LSD-25 intoxication resemble aspects peculiar to schizophrenia[1,2]. As a result, the drug has been utilized as an effective tool to explore the induction of reversible psychoses in non-psychotic subjects. It has been assumed that the similarities produced by LSD-25 could yield information pertinent to the mechanisms and pathophysiology involved in schizophrenia[2,3].

Various investigators have explored the effect of LSD-25 on the pituitary-adrenal axis using as parameters alterations in the total leukocytic[4] and eosinophilic levels[4,5]. Decreases in the frequencies of these cell types have been frequently associated with increased adreno-cortical activity[4,6]. In general, the literature contains contradictions and inconsistencies concerning the effects of LSD-25 on the white blood cells. Much of this is attributable to differences in dosage, method of administration, small samples and species variations. In addition, several investigations involved changes observed in and complicated by psychotic states. To illustrate, Forrer *et al.*[1] reported that LSD-25 induced transitory leukocytosis in schizophrenic patients. Rothlin *et al.*[7] similarly claimed leukocytotic changes in test rabbits. Although Feld *et al.*[5] observed lowered eosinophil-levels in normal and abnormal subjects, others failed to note eosinopenia either in man[8] or in rats[9]. Belsanti[10], however, analysing differential blood slides, reported that LSD-25 caused relative eosinopenia, lymphopenia and neutrophilia in schizophrenic patients. Others[4] have claimed significant eosinopenia with evidence of marked relative and absolute neutrophilia in injected guinea pigs.

The work recorded here was undertaken to determine the effects produced by prolonged administration of LSD-25 on adrenal activity by evaluating the alterations in total leukocyte, eosinophil and differential blood cell counts of female rats.

Forty-eight female Wistar rats averaging 100 g in bodyweight were divided equally into 3 groups. (All rats were housed singly in metabolism cages. The room temperature maintained by an air-conditioning system ranged from 22°–25° C. The average level of the laboratory background noise during the period of experimentation was 68 decibels during the daylight hours[19,20].) Group *A* and *B* rats were injected subcutaneously with 50 and 75 μg of LSD-25 dissolved in normal saline. Group *C* control animals received an equivalent 1 ml. dose of saline. To diminish tolerance effects, eight injections were administered over a 2-week period on alternate days. On the thirteenth and fourteenth day, the rats received consecutive daily injections. Twenty-four hours after the last injection, blood samples were obtained from the tail. Standard techniques were used for total leukocyte[11] and eosinophil[12] counts. The differential blood slides were stained with MacNeal tetrachrome solution and analyses were based on counts of 200 cells per animal.

Table 1 lists the changes produced by LSD-25 administered over a two-week period. Doses of 50 μg induced a significant 34·4 per cent decrease in the eosinophils of group *A* rats, as compared with control animals. The decrease in total leukocyte frequencies approached significance (0·09). Administration of 75 μg yielded a markedly significant decrease in leukocytic frequencies (0·01) with eosinophilic declines slightly less than that observed in group *A* rats (33·1 per cent). In both groups, comparisons of the differential data with the controls (Table 2) indicated a slight trend towards relative lymphopenia, eosinopenia and neutrophilia. Analyses of the absolute values revealed a lymphopenia ranging from 18·3 to 24·8 per cent for group *A* and *B* rats and absolute eosinopenia ranging from 41·3 to 32·0 per cent for the LSD-25 treated groups. Although group *B* data revealed a decline in the frequencies of the neutrophils, group *A* results indicated little or no change in the absolute neutrophil numbers. Depressions were noted in the lymphocyte/neutrophil ratios of group *A* and *B* rats. In general, the data are in accord with other investigations reporting induction of eosinopenia[4,5,10] and lymphopenia[10] by LSD-25.

The various leukocytic alterations thus agree with changes usually characteristic of non-specific stressors. The work recorded here consequently supports, and is in agreement with, reports that LSD-25 has a stimulatory effect on adrenal function. The study also suggests a

relationship of LSD-25 intoxication responses to schizophrenia which may go beyond mere psychomimetic similarities. Various investigators have observed lowered eosinophil-levels in the blood of schizophrenic patients[13,14]. Sackler *et al.*[13,15,16] reported marked increases in the eosinophils and rises in the lymphocyte-neutrophil ratios of schizophrenic patients showing the greatest clinical improvement with sex steroid therapy. Altschule[14], similarly, reported eosinophil elevations in schizophrenics given pineal extract injections. Thus, the present evidence of a stimulatory effect on the adrenals by the hallucinogenic drug LSD-25 parallels and adds support to the Sackler *et al.* hypothesis[17,18] that relative and operative hyperadrenocorticalism with concomitant relative or absolute hormonal deficiencies, such as hypothyroidism and/or hypogonadism, may be a possible ætiologic and pathogenetic factor in at least one sub-group of schizophrenia.

We thank Sandoz Pharmaceuticals, Hanover, New Jersey, for supplying the LSD-25.

HÆMATOLOGY

Cytochemical Demonstration of Aminopeptidase Activity in Blood Platelets

A NUMBER of enzymes have been identified biochemically in platelets[1] and several of these have been localized cytochemically[1,2] as well. Aminopeptidase activity also can be demonstrated in platelets by an adaptation of Burstone's histochemical method[3,4].

Blood smears of healthy adult persons were briefly dried at room temperature and then fixed in cold acetone at 4° C for 1 h. Following this they were incubated for 22 h at room temperature in an incubating medium composed of 4 mg of alanyl-β-naphthylamide dissolved in 5 ml. of distilled water, 5 ml. of 0·1 M Sörensen's phosphate buffer at *p*H 6·8, 1 mg of magnesium sulphate and 5 mg of fast garnet *GBC*. An alternate, otherwise similar incubation medium contained 4 mg of 'Leucine' β-naphthylamide instead of alanyl beta-naphthylamide, and 1 mg of potassium cyanide instead of magnesium sulphate. After incubation in either of the foregoing solutions, the coverslips were rinsed for 10 min in tap water, briefly fixed in 10 per cent neutral formalin and mounted in glycerogel.

Microscopic examination of these preparations revealed fine granular orange red to rusty brown deposits in all platelets, an indication of considerable aminopeptidase activity (Fig. 1). A more intense reaction was seen with alanyl-β-naphthylamide, while incubation in medium from which the substrate was omitted yielded no evidence of enzymatic activity. Leukocytes also displayed aminopeptidase activity as described by Ackerman[5].

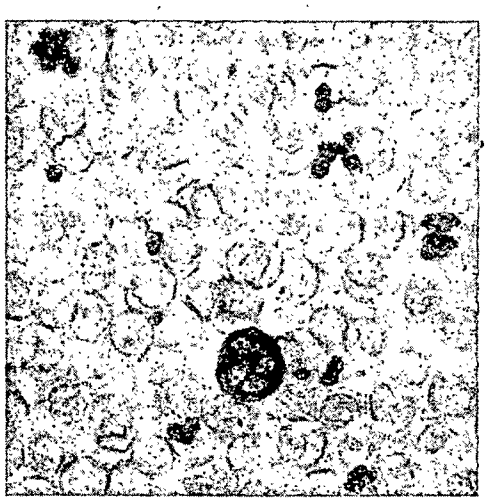

Fig. 1. Showing considerable aminopeptidase activity in human blood platelets (incubated in alanyl-β-naphthylamide). A neutrophilic leukocyte also reveals strong enzyme activity. (× 700)

The significance of the presence of aminopeptidases in platelets is uncertain, although as noted earlier their occurrence has been known for some time[6,7]. Recently Kocholaty[8], for example, has characterized several di- and tri-peptidases in normal human platelets. A more intense reaction was found with alanyl β-naphthylamide, but it is unlikely that this represents a difference in specific aminopeptidase-level in the platelets. From reports on other tissues[9,10] it would appear that more than one aminopeptidase may participate in histochemical reactions using chromogenic aminoacyl-naphthylamides, even though certain peptides may be preferentially hydrolysed. On the other hand, an increased peptidase activity has been reported in platelets during menstruation and in some hæmorrhagic disorders[11], while enzyme-levels decreased during the administration of dicoumarol[12]. These data tend to link aminopeptidase activity in platelets with blood clotting phenomena, but the true physiological role of these enzymes in platelets remains unknown.

This investigation was supported by a grant (*NB*–04155–02) from the National Institute of Neurological Diseases and Blindness, National Institutes of Health of the United States Public Health Service, Bethesda, Maryland.

Elution Procedure for the Demonstration of Methæmoglobin in Red Cells of Human Blood Smears

THE peroxidatic activity of the red blood pigment can be inhibited by cyanide in the case of methæmoglobin (Hb^{III}), but not in the case of oxyhæmoglobin (Hb^{II}) (ref. 1). It seemed promising to use this difference for a differential staining procedure of Hb^{II}- and Hb^{III}-containing red cells by first adding cyanide to the heparinized or citrated blood in question and by staining smears prepared from it by a peroxidase reaction.

The results were relatively poor. Much better results were obtained, however, with the following elution procedure:

(1) To heparinized or citrated blood 1/50 vol. of a 0·4 M solution of potassium cyanide is added. Thin blood smears are prepared.

(2) The air-dried smears are immersed into the following mixture at room temperature: 80 ml. ethanol (96 per cent); 16 ml. 0·2 M citric acid; 5 ml. hydrogen peroxide (30 per cent b.w.). The smears are agitated up and down for 1 min and then allowed to stand for 2 min.

(3) Washing first in methanol, then in water, 30 sec each.

(4) Staining for 2 min in Ehrlich's hæmatoxylin and, after rinsing with tap water, for 2 min in 0·2 per cent erythrosin (Merck). Rinsing and drying.

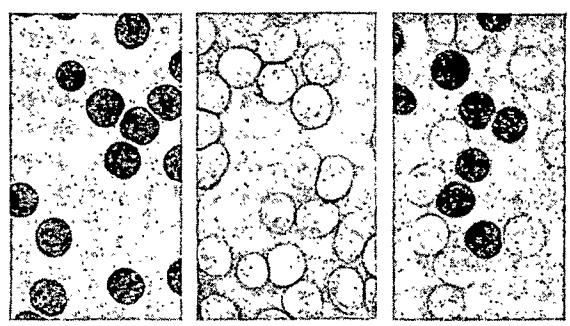

Fig. 1. Elution and staining of blood smears for the demonstration of methæmoglobin. Left, normal human adult blood; middle, same blood after preliminary conversion of the blood pigment to methæmoglobin by nitrite; right, mixture of normal and methæmoglobinæmic blood

Hb^{II}-containing red cells are stained red; Hb^{III}-containing cells are eluted and appear as ghosts (Fig. 1). The reaction is not fully understood. Since (*a*) Hb^{III} is not eluted without adding potassium cyanide to the blood; (*b*) both Hb^{II} and Hb^{III} are eluted if hydrogen peroxide is not present in the mixture; (*c*) neither Hb^{II} nor Hb^{III} is eluted without citric acid in the mixture, it seems that peroxidatic or catalatic reaction of hydrogen peroxide with the blood pigment prevents elution by citric acid. The possibility that red cell catalase could play a part was excluded, for acatalatic blood (generously provided by Prof. Takahara (Okayama) and Dr. Lejeune (Lausanne)) behaved like normal blood.

The method is not suitable for the exact estimation of methæmoglobin-levels in blood. However, it gives useful information concerning experimental oxidation and reduction of the blood pigment within the red cells.

Bilirubin and Coagulation of Blood

Free bilirubin, dissolved in sodium carbonate, causes, if given intracardially to rabbits, a pronounced lessening of the plasmatic clotting-activity. Among other effects, prolongation of the heparin-tolerance- and recalcification-times (Howell-time) as well as lowering of the factors II and VII occur[1].

We tried to determine if *in vitro* addition of bilirubin to normal human citrated plasma also influences the clotting mechanism[2].

Free bilirubin at physiological *p*H is not very soluble in plasma. Therefore we dissolved bilirubin (50 mg bilirubin 'Homburg') in a sodium carbonate solution (0·185 g in 10 ml. water). This solution was then added to normal plasma (at a ratio of about 1 : 5). Bilirubin- and pure carbonate-plasma (control plasma) were afterwards each dialysed for 24 h, put into barbital buffer-solution *p*H 7·4 and into saline. The *p*H afterwards ranged between 7·1 and 7·5. The bilirubin concentration in the bilirubin plasma figured up to 70 mg per cent; in the control plasma it was less than 1 mg per cent. Excessive, non-albumin-bound, bilirubin was eliminated by centrifugation.

Prior to the test the bilirubin plasma was mixed with normal plasma, resulting in bilirubin concentrations of 10, 20, 30, 40, 50 and 60 mg per cent. The control plasma was added to the same normal plasma in corresponding volume parts. The activity of factors II, V, VII, VIII, IX and X was tested, also the thromboplastin- and recalcification-time as well as antithrombin II and profibrinolysin. The entire number of mixtures tested was 14, that is, bilirubin plasma in normal plasma and control plasma in normal plasma. All reaction-times were measured 10 times, and the results statistically evaluated.

Our results allow comparison between plasmas with and without added bilirubin as regards several qualities of coagulation. The reaction times measured showed no significant differences. Non-conjugated bilirubin remains in our experimental set-up even up to concentrations of 60 mg per cent without provable influence on plasmatic coagulation. Factor V is an exception. This factor displays a slight lessening in activity at concentrations of bilirubin above 20 mg per cent. The prolongation of the reaction-time, however, does not amount to more than 8 per cent.

The differing results of the experiments *in vitro* and those on the living organism demand further clarification. If animal and human plasma do not in principle react differently, one must presume that bilirubin may influence the site of production of certain coagulation factors and thereby cause a weakening of the coagulation potential.

IMMUNOLOGY

Character and Allotypy of an Immune Globulin in Rabbit Colostrum

Rabbit serum β_2-macroglobulin and its relation to γ-globulin have been previously described[1]. This communication describes the demonstration and characterization of a third immune globulin, found in rabbit colostrum.

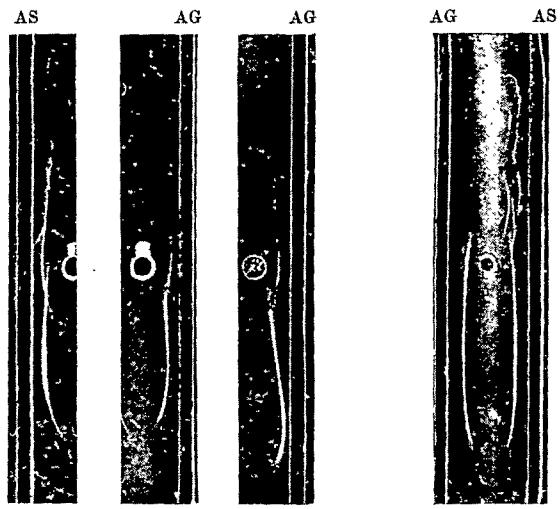

Fig. 1. Immunoelectrophoretic patterns of (*a*) rabbit colostra, (*b*) rabbit serum. Slots were filled with either anti-serum AS (goat anti-rabbit serum globulins) or AG (goat anti-rabbit γ-globulin)

When developed with a highly specific goat anti-serum (AG) to chromatographically purified rabbit γ-globulin, the immunoelectrophoretic pattern of rabbit serum showed only a single γ-globulin arc (Fig. 1*b*). Rabbit colostrum (Fig. 1*a*) gave the γ-globulin arc, but in addition a second arc with the mobility of a fast β-globulin. This immune β-globulin does not, however, precipitate all the anti-γ-globulin, since a forward spur is formed where the two arcs meet. When a less-specific goat anti-serum (AS) to rabbit serum globulins was used to develop the colostral pattern (Fig. 1*a*) the β- and γ-immune globulin arcs crossed; this shows that antibodies specific for the β- and for the γ-immune globulin were present in AS. The β-globulin was evidently present in the rabbit serum globulins used to prepare goat anti-serum AS. When the colostral pattern was developed using anti-serum AG, which had been previously absorbed with either fragment I (ref. 2) of papain hydrolysed γ-globulin or the separated *B* (light) chains[3] of rabbit γ-globulin (Fig. 2), the β-globulin arc did not develop, and only the γ-globulin arc appeared. This shows that the β-immune globulin possesses *B* chains antigenically identical with those of γ-globulin, but lacks other structural components of γ-globulin.

The β-globulin is distinguishable from β_{2M} globulin by its faster mobility[1], but might correspond to the third immune globulin, β_{2A} globulin, identified in human serum[4], particularly as this serum component has been found to

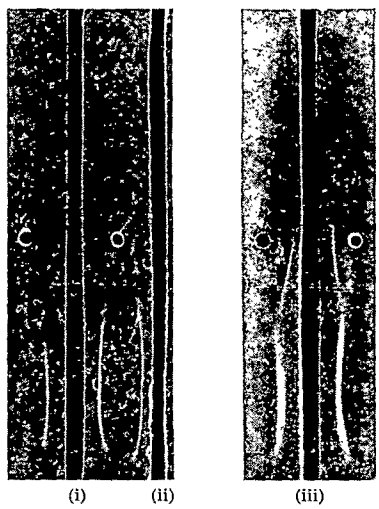

Fig. 2. Immunoelectrophoretic patterns of rabbit colostra. Slots were filled with (i) goat anti-rabbit γ-globulin serum (AG) absorbed with fragment I from papain-treated γ-globulin; (ii) AG absorbed with *B* (light) γ-globulin chains; (iii) AG untreated

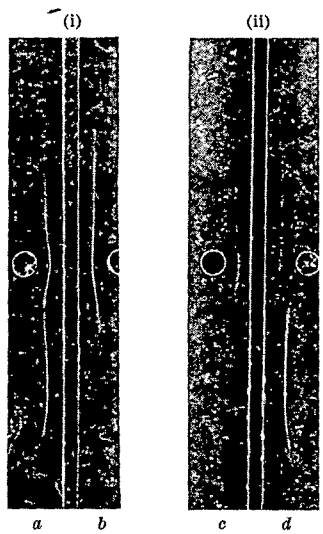

Fig. 3. Immunoelectrophoretic patterns. (*a*), (*d*), Rabbit colostrum; (*b*), (*c*), rabbit colostrum supernatant after zinc precipitation. Slots were filled with (i) anti-*A*4 allotypic anti-serum; (ii) goat anti-rabbit γ-globulin serum (AG)

be selectively concentrated into human colostrum[5]. Heremans[6] showed that γ-globulin can be selectively precipitated from human serum by zinc to give a relative enrichment of the β_{2A} component in the supernatant. The same fractionation method was applied to rabbit colostrum. Figs. 3*c* and *d* show a comparison of the immunoelectrophoretic patterns of the original colostrum and of the concentrated supernatant after zinc precipitation. The relative reduction in γ-globulin content is rather more evident when the two patterns (Figs. 3*a* and *b*) are compared after development with an allotypic anti-γ-globulin serum (anti-*A*4)[7]. This confirms the similarity between the rabbit β-globulin and human β_{2A} globulin.

The β- and γ-globulins were separated, using a column of 'Sephadex *G*200', when the β-globulin was eluted first. The immunoelectrophoretic patterns of the separated fractions are seen in Fig. 4. This fractionation, on the basis of size difference, may be successful only because, as many workers have shown with its human counterpart[6,8], the rabbit β-globulin is aggregated, or associated with other proteins. An equally complete separation was also achieved using an anionic exchanger, DEAE-cellulose.

Allotypic anti-sera, monospecific for the various genetically determined types of rabbit γ-globulin, were generously supplied by Dr. A. Kelus. Using these, the immunoelectrophoretic patterns were developed of colostra from rabbits of known allotype. Typical examples are shown in Fig. 5, exhibiting allotypic specificities *A*1 (Fig. 5*a*), *A*2 (Fig. 5*b*), *A*3 (Figs. 5*c* and *d*), *A*4 (Fig. 5*e*) and *A*5 (Fig. 5*f*). With anti-*A*4 and anti-*A*5 the β-globulin formed a precipitin line comparable in strength to that of the γ-globulin. With the specific anti-sera to *A*1 and *A*2 the line was rather weaker, and, in the case of *A*3, almost undetectable.

It is believed that the allotypic specificities *A*1, *A*2 and *A*3 are governed by allelic genes at one locus (*a*), and *A*4, *A*5 and *A*6 are governed at another locus (*b*)[7]. It is, therefore, interesting that all the specificities tested for were present in both β- and γ-globulins. Thus, although the cross-reactions with goat anti-sera revealed only that *B* (light) chain was common to both immune globulins, structural features controlled by two independent loci are now seen to be shared. Only specificities *A*4, *A*5 and *A*6 have been found on the separated *B* (light) chains[9]. It appears likely, therefore, that immune globulins, besides sharing a common light chain controlled by the (*b*) locus, may also have a common sub-unit, possibly bearing the specific antibody site, controlled by the (*a*) locus. This would be consistent with a similar finding recently reported

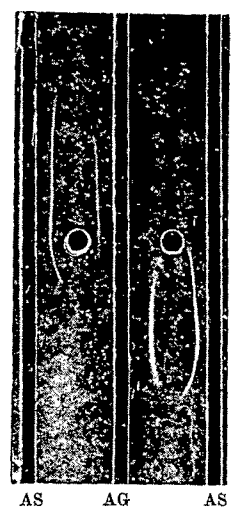

Fig. 4. Immunoelectrophoretic patterns of two rabbit colostrum fractions separated on 'Sephadex G200' gel. Slots were filled with either anti-serum AS (goat anti-rabbit serum globulins) or AG (goat anti-rabbit γ-globulin)

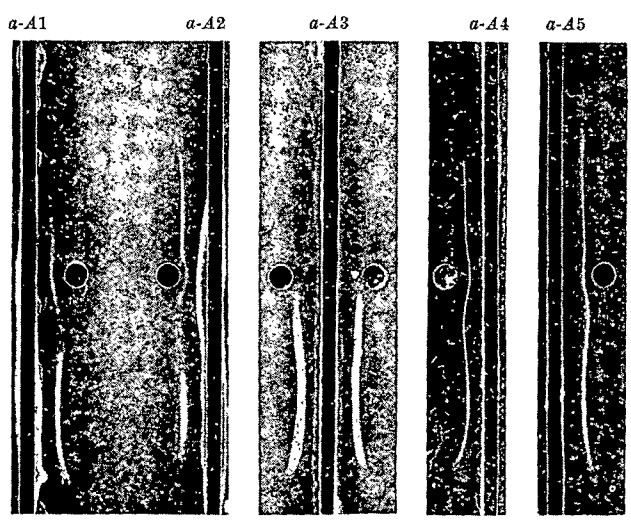

Fig. 5. Immunoelectrophoretic patterns of rabbit colostra. The patterns were developed using the following allotypic anti-sera in the slots; for (*a*) anti-*A*1 (*a*—*A*1); (*b*) *a*—*A*2; (*c*) and (*d*) *a*—*A*3; (*e*) *a*—*A*4; (*f*) *a*—*A*5

for the allotypes in rabbit serum macroglobulin preparations[10]. However, alternative theories must first be examined; for example, it will be necessary to see whether some allotypic determinants are prosthetic groups rather than part of the main polypeptide configuration.

Immunoglobulin Abnormalities of the Thymectomized Rat

WE have shown that the adult rat, thymectomized at birth, has a global defect in delayed hypersensitive responses correlated with a depletion of small lymphocytes from blood, lymph nodes and spleen[1]. The deficiency in antibody mediated responses, in contrast, is selective. The nature of this latter defect has not been clarified. It has been shown that plasma cell and serum γ-globulin levels are normal in thymectomized rats[2].

WAG (Wistar) rats were thymectomized, or sham thymectomized, at 2–3 days of age by our usual technique[3]. At 8–12 weeks of age they were bled by cardiac puncture and the sera analysed immunoelectrophoretically. Total and differential white cell counts were done on tail blood. For the preparation of rabbit antisera, pooled normal rat serum in saline was emulsified with an equal volume of mycobacterial adjuvant (Difco) and 0·4 ml. of the mixture (1 mg protein) was given into the toe pads of all 4 feet. Six weeks later, after a precautionary subcutaneous injection of 1 mg normal rat serum, all animals were boosted intravenously with 2 mg normal rat serum in 1·0 ml. saline. Seven days later they were bled. Immunoelectrophoreses were carried out by standard methods[4]. To demonstrate more clearly the β_2M macroglobulin (*IgM*), the rabbit antisera were absorbed with a rat γ- and β-globulin fraction, the preparation of which is given elsewhere[5]. The identity of *IgM* was established by the cysteine degradation technique[6]. A pool of rat antisera against bovine serum albumin was precipitated at equivalence with bovine serum albumin and the specific precipitate washed six times. Rabbit anti-rat serum was absorbed with the specific precipitate before being reacted against normal rat serum in immunoelectrophoresis. In a separate experiment, the rabbit anti-serum was absorbed with normal new-born rat serum and then reacted against normal rat serum in immunoelectrophoresis.

Immunoelectrophoresis failed to reveal any abnormality of serum γ-globulin (*IgG*) levels in thymectomized rats.

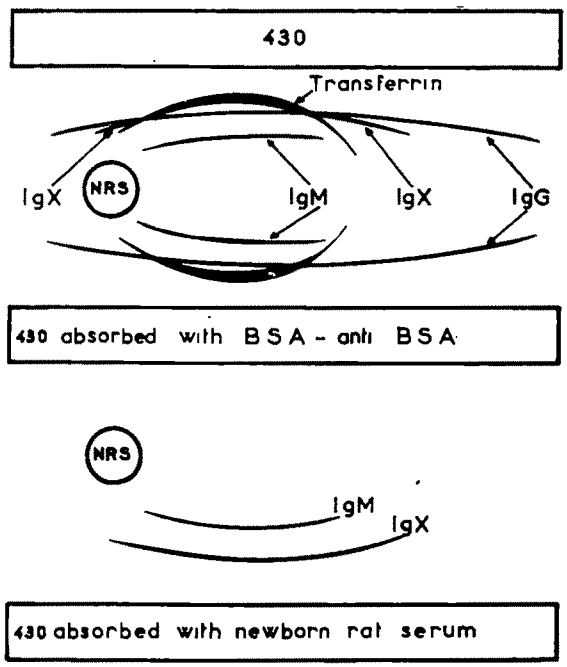

Fig. 1. Immunoelectrophoresis of normal rat serum (NRS) against rabbit – anti-rat serum (430)

IgM levels were increased in 7/8 thymectomized rats as compared to 8 sham-operated litter mate controls.

In 8/9 control rats 8–12 weeks of age, and invariably in older rats, a third immunoglobulin was detected which we have tentatively chosen to call *IgX*, and which corresponds, in all probability, to the protein designated β_{2A} by Escribano[7]. *IgX* extended cathodally into the slow β-region; anodally it extended medial to *IgG* well into the α-region (Fig. 1). Its central portion was generally hidden by the *IgG* line. It could be demonstrated in pooled normal rat serum diluted to 0·25 but not at a dilution of 0·125. In 7/14 thymectomized rats, aged 8–12 weeks, using undiluted serum, this protein line could not be detected; in a further 6, its intensity was markedly diminished. In some thymectomized rats *IgX* was still absent at 19 weeks. There was a direct correlation between the extent of lymphocyte depletion and the *IgX* deficiency (Table 1).

Rat antibody against bovine serum albumin gives a single precipitin line on diffusion in gel against bovine serum albumin. The antigen-antibody complex gives a reaction of non-identity with rat *IgG* and *IgM*. Absorption of rabbit anti-rat serum with bovine serum albumin–rat anti-bovine serum albumin specific precipitate removes the *IgX* line and no other (Fig. 1). *IgX* is not seen in sera of normal rats aged less than 6 weeks. Absorption of rabbit anti-rat serum with new-born rat serum removes all negatively migrating precipitin lines except *IgM* and *IgX* (Fig. 1).

We have shown that the thymectomized rat has a severely compromised capacity to form antibodies against bovine serum albumin. This defect would appear to be related to a deficiency in *IgX* rather than in *IgG* or *IgM*

Table 1. IMMUNOELECTROPHORETIC ANALYSIS OF *IgX* LEVELS IN THYMECTOMIZED AND SHAM-OPERATED RATS 8–12 WEEKS OF AGE

Group	*IgX* precipitin line					
	Absent		Diminished		Normal	
	No. of animals	Lymphocyte count*	No. of animals	Lymphocyte count	No. of animals	Lymphocyte count
Thymectomized	7	4,200 (2,500–5,700)	6	6,600 (5,600–7,700)	1	7,000
Sham operated	1†	15,400	0	—	8	15,800 (10,200–22,200)

* Average count—range in parentheses.
† This animal also had hypogammaglobulinæmia.

synthesis. No counterpart in the rat of human *IgA* (β_2A-globulin) has thus far been identified. Whether the *IgX* which we have found in the rat is analogous to the *IgA* of human serum remains to be established, as does a more precise delineation of its relationship to lymphocytes and to delayed sensitivity.

Identification of a Somatic Antigen of *Staphylococcus aureus* Critical for Phagocytosis by Human Blood Leucocytes

The capacity of *Staphylococcus aureus* to produce disease resides in its ability to invade and persist in the body, and in its elaboration of toxic metabolites. Host-defensive mechanisms comprise the elaboration of antibodies which facilitate phagocytosis and intracellular destruction, and the elaboration of antitoxins. This communication reports identification of at least one antigen of the staphylococcal cell-wall which is critical for phagocytosis by human blood leucocytes.

We have identified previously[1] a non-type-specific protein agglutinogen of the staphylococcal cell-wall. The antibody homologous with this antigen can, however, be absorbed out of human serum without impairing the ability of the serum to promote phagocytosis[2]. Combination of the serum antibody with a soluble carbohydrate antigen, teichoic acid, we now find does remove the phagocytosis-promoting action of human sera.

The teichoic acid may be extracted from staphylococcal cell-walls by standard methods[3,4]. The teichoic acid used for absorption of antibody in the representative experiment shown in Fig. 1 was prepared as follows:

Undigested staphylococcal cell-walls were prepared from staphylococci of International Serotype XIII by disintegration in an 'X-press' and purification by gradient and pile centrifugation[6,7]. Teichoic acid was then extracted from the undigested cell-walls essentially as described by Morse[4]. Removal of the serum components responsible for phagocytosis and killing of staphylococcal cells by human blood leucocytes by absorption with this preparation is shown in Fig. 1.

Carbohydrates were also prepared from acetone-dried cells of *Staph. aureus* by methods in principle those of Baddiley, Armstrong and Buchanan[8]. Absorption of human sera by this teichoic acid removed phagocytosis-promoting antibody from human sera.

Baddiley, Buchanan, Martin and RajBhandary[9] and Baddiley[10] have shown that the cell-wall teichoic acid of *Staph. aureus H* is a polymer of ribitol phosphate with side-chains of *N*-acetyl-D-glucosamine attached to position 4 and D-alanine in ester linkage at position 2 or 3 of D-ribitol. Morse[4] has shown that antibody against teichoic acid of *Staph. aureus* (strain *NYH*-6) can be inhibited in the precipitation and hæmagglutination reaction by β-phenyl-N-acetylglucosamine. Sanderson, Juergens and Strominger[11] have shown that the agglutination of cell-walls of *Staph. aureus*, strain Copenhagen, can be inhibited by α-phenyl-acetylglucosaminide. (See also refs. 12 and 13.)

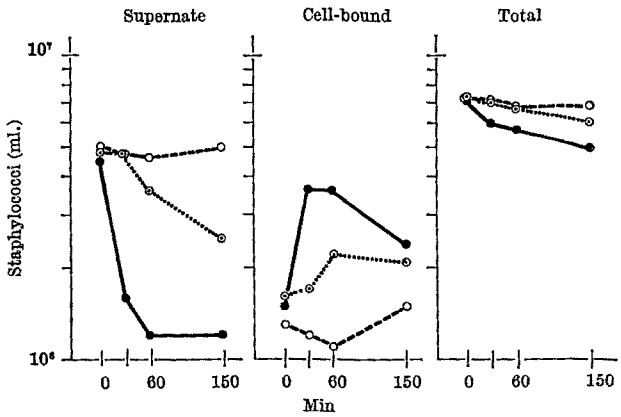

Fig. 1. Phagocytosis of staphylococcal cells (International Serotype XIII) by human blood leucocytes (Type 0) in presence of fresh human serum (Type 0) and of human serum absorbed with teichoic acid extracted from homologous staphylococcal cell walls (25 mg/ml. of 1/10 serum). Phagocytic technique adapted from Cohn and Morse (ref. 5), as described by Li, Mudd and Kapral (ref. 2). Ordinates record viable staphylococci/ml. recovered at successive times respectively from the supernatant fluid, the centrifugal sediment after lysis of leucocytes, and from the entire phagocytic system after lysis of leucocytes. First extraction: Teichoic acid obtained from first 24-h extraction with 5 per cent trichloroacetic acid in the cold. Second extraction: Teichoic acid obtained from successive 48-h extraction with 5 per cent trichloroacetic acid in the cold. Absorption removes partially or wholly both phagocytosis promoting and killing effect of fresh serum. ●, 1 per cent fresh serum; ○, 1 per cent fresh serum absorbed with teichoic acid (first extraction); ⊙, 1 per cent fresh serum absorbed with teichoic acid (second extraction)

In other investigations it has been shown that *N*-acetyl-D-glucosaminide is required for the synthesis of the muramic acid of normal cell-walls of *Lactobacillus bifidus* var. *Pennsylvanicus*[14,15]. Derivatives of *N*-acetyl glucosamine (which are growth factors for *L. bifidus* var. *Penn.*) were generously made available to us by Dr. M. C. Glick. An anomeric mixture of α-(85 per cent), β-(15 per cent) methyl-*N*-acetyl-D-glucosaminide partially inhibited the antibody in human sera promoting phagocytosis of *Staph. aureus* by human blood leucocytes (Fig. 2). A sample of β-ethyl-*N*-acetyl-D-glucosamine[16], 25 mg/ml. of 10 per cent heated human serum, also partially inhibited phagocytosis of *Staph. aureus* serotype XIII. 4-*O*-β-D-galactopyranosyl-*N*-acetyl-D-glucosamine (*N*-acetyl lactosamine) did not inhibit phagocytosis. Our experiments with *N*-acetyl-D-glucosamine encountered complications and did not yield a clear result.

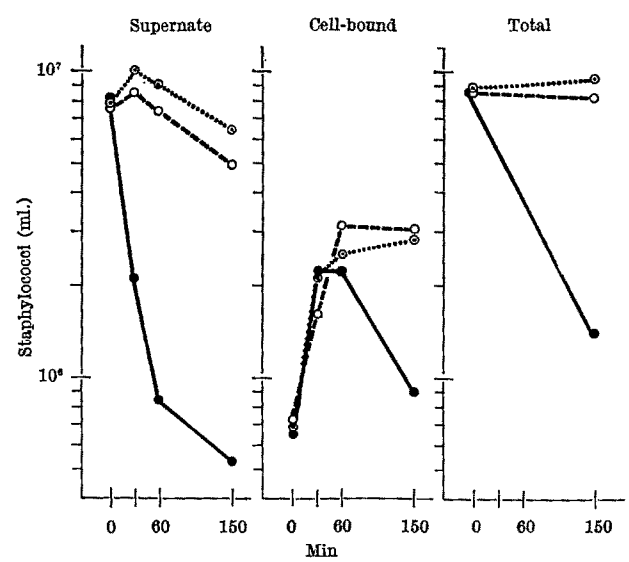

Fig. 2. Inhibition of phagocytosis and killing of staphylococcal cells (Serotype XIII) by absorption of fresh human serum with α,β-methyl-*N*-acetyl-D-glucosaminide. Type 0 serum; Type 0 cells. Solid line, 1 per cent fresh serum; broken line, 1 per cent fresh serum absorbed with 25 mg/ml. of 10 per cent serum; dotted line, 1 per cent fresh serum absorbed with 100 mg/ml. of 10 per cent serum

We have observed that human serum inactivated by heating to 56° promotes phagocytosis to a less degree than fresh serum and fails to produce intracellular killing of *Staph. aureus*[2]. In Fig. 2 it may be seen that the α,β-methyl-*N*-acetyl-D-glucosaminide inhibits killing as well as phagocytosis by human blood leucocytes. This result is compatible with the accessory killing factor being complement.

PATHOLOGY

Induction of Melanotic Lesions of the Iris in Rats by Urethane given during the Neonatal Period

THERE have been a number of reports in recent months of experiments in which animals have been exposed to chemical carcinogenic agents during the neonatal period[1–6]. It is probable that, on the basis of dose per unit of body-weight, newly born animals are particularly sensitive to tumour-induction. For example, lung tumours may be very readily induced in mice by the neonatal injection of small doses of certain weakly carcinogenic agents[4]. Because of this high sensitivity, the use of newly born animals for screening for carcinogenicity has been suggested[3]. Of possibly even greater interest, however, is the fact that animals injected when newly born with carcinogenic agents develop varieties of neoplasms not seen when the same agents are injected into adults of the same species and strain. For example, newly born '101' strain mice injected with small doses of 9,10-dimethyl-1,2-benz-anthracene developed kidney tumours[3]. A further example of this type of phenomenon has recently come to light in an experiment in which rats were injected during the neonatal period with urethane (ethyl carbamate).

Urethane was already known to be capable of inducing neoplastic lesions in a wide variety of tissues[7–9]. The purpose of the experiment, details of which are given in Table 1, was simply to examine the effects of neonatally administered urethane in two strains of rat, the August Hooded and Wistar. The rats used were from sub-lines maintained for several years in the Institute by brother–sister mating. Fifty-one August rats (26 ♀ and 25 ♂) and 44 Wistar rats (21 ♀ and 23 ♂) constituted the two experimental groups. The former were derived from eight different litters and the latter from six. Similar numbers of litters born at about the same time were kept under observation without treatment as controls.

Table 1. INCIDENCE OF MELANOTIC LESIONS OF THE IRIS IN RATS TREATED WITH URETHANE DURING THE NEONATAL PERIOD

(1 mg/g body-weight once weekly for 8 weeks, the first injection being given during the first 24 h of life)

Wistar	50	25 ♀ 25 ♂	0‡	0	0	0	0	0

* 10 per cent w/v in sterile distilled water.
† After 9 months from the start of the experiment.
‡ Control animals were untreated.
§ These were untreated rats of between 9 and 12 months of age. In every other way they were comparable to both the preceding groups.

During the seventh month of the experiment one of the members of the staff of the animal unit, Mr. Malcolm Kipling, observed that a number of the August rats, which had been treated with urethane when young, had 'dark spots' in their eyes. Thereupon a careful examination of all the rats in the experiment was undertaken. 'Dark spots' were observed in the eyes of 11 females and 7 males of the urethane-treated August rats, both eyes being involved in 5 of the rats. None of the 50 control August rats showed lesions. Moreover, no lesions were found in 200 untreated August rats of similar or older age. No lesions were seen in rats of the Wistar strain whether treated with urethane or not. During a further two-month period of observation 2 more August rats in the urethane-treated group have developed lesions: 1 male and 1 female. Ophthalmoscopic examination showed that the lesions were located in the iris and that they were fan-shaped when the pupil was small. When the pupils were dilated, however, the lesions appeared as a thin black ring extending around a part of the periphery of the anterior chamber.

Two of the rats were killed and their eyes taken for histological examination. In each case the lesion proved to consist of pigment-containing cells situated in the connective tissue between the two epithelial surfaces of the iris. The presence of these cells increased the thickness of the iris up to three-fold (Figs. 1 and 2). The pigment could be removed by bleaching with hydrogen peroxide, indicating that it was probably melanin. Very few mitotic figures were seen and there was no evidence of invasive-

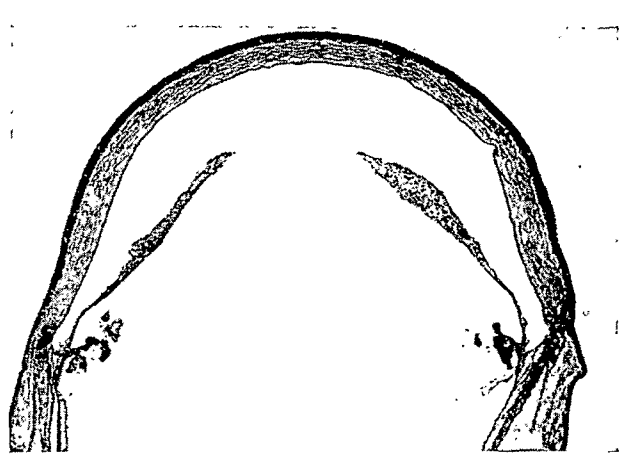

Fig. 1. Eye from seven-months-old urethane-treated August rat. The lens has been removed and the ciliary body and iris remain on either side. The thickening of the iris on the right side is associated with the presence of pigmented cells (hæmatoxylin and eosin. × 20)

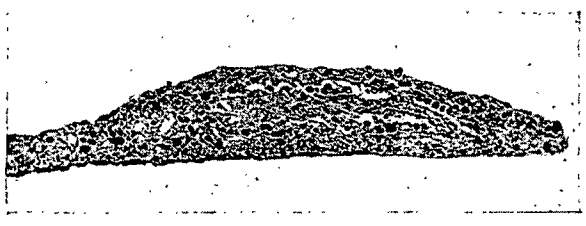

Fig. 2. Melanotic lesion of the iris from a seven-month-old August rat. (A different rat from that illustrated in Fig. 1.) Melanocytes are distributed widely in the connective tissue (hæmatoxylin and eosin. × 80)

ness. The fact that the pigmented cells were in the connective tissue and not in the epithelial layers, as well as consideration of the other features already mentioned, led us to the view that the lesions were naevi rather than melanomas, and that the pigmented cells were naevus cells (melanocytes) and not melanoblasts. We suspect, therefore, that the lesions have only a low potentiality for malignant change. A few rats have died in all the groups from lung infections, and two of the urethane-treated August rats have died from lymphatic leukæmia (malignant lymphoma of the stem cell type). No neoplasms were seen at post-mortem in any of the other rats which died or were killed. The rest of the animals in the experiment are being kept under observation.

We felt that these data were of sufficient interest to present in preliminary form for several reasons. First, there are but few examples of the experimental induction of melanotic neoplasms, though the Syrian Golden hamster appears to be especially apt to develop tumours of this type[10,11]. In 1960 Pietra and Shubik[11] reported the induction of melanotic lesions of the skin in hamsters treated with urethane in the drinking water. In their experiments the males developed a higher incidence of lesions than the females. Other reports of melanoma induction by chemical agents are mentioned by Della Porta *et al.*[10], and reviewed by Nakai and Rappaport[12]. The latter authors describe the melanotic tumours which they were able to induce in the Syrian Golden hamster by the application of 9,10-dimethyl-1,2-benzanthracene (DMBA) to the skin as consisting of dendritic melanocytes situated in the dermis. They thought the lesions resembled either cellular blue naevi or pigmented neurofibromas of man. These 'induced' lesions are quite different from the malignant melanomas which occasionally arise spontaneously in the Syrian Golden hamster[13]. The latter always involve the dermoepidermal junction. We have little doubt that the lesions seen by us were akin to these DMBA-induced tumours. We could find no record anywhere in the literature of the experimental induction of neoplastic lesions of the iris: Hartwell[14] and Shubik and Hartwell[15] list none.

Secondly, there seems to be some confusion among ophthalmic surgeons concerning the nature, malignancy potential, and best method of treatment of pigmented lesions of the iris. For example, in 1951, Reese[16] wrote, "It is certain that malignant melanomas of the iris develop from pre-existing benign melanomas. I have observed such metamorphoses, and in a number of cases in the literature (10 references given by author at this point) there is from early youth a clear history of pigmented lesions from which malignant melanomas develop". Eleven years later, Ilif and Ossofsky[17], writing on the same subject, expressed the following views: "Nevi are the most common tumors of the iris . . . The tumors never attain great size and no therapy is indicated . . . Although it is claimed that nevi are potentially malignant, it is felt that benign nevi of the iris arising in childhood rarely, if ever, undergo malignant change, and that melanomas of the iris do not arise from a pre-existing nevus but are malignant from the start". Similarly, Zimmerman[18], after describing the clinical and pathological varieties of iris tumour, wrote: "The usual iris tumors falling into the nevus-melanoma group are either completely benign nevi or relatively benign spindle cell melanomas". He, too, stresses the uncertainty among ophthalmic surgeons as to the best method of management of cases of iris tumour.

A third reason why the production of the lesions described in this communication may be important is that the eye, with its normally transparent media, provides an unusual opportunity to make direct *in vivo* observations of tumour growth. "This," says Zimmerman[18], "is particularly true in the case of tumors of the iris, which may even be examined microscopically in the living eye with the use of magnification of 8× to 40× or more."

A Lactic Dehydrogenase Elevating Agent in Association with Human Neoplasms

The observation that a variety of murine neoplasms contain a filterable agent capable of inducing a five- to ten-fold increase in plasma lactic dehydrogenase (LDH) activity within 48 h of inoculation into normal mice was reported by Riley *et al.*[1], and confirmed by Mundy and Williams[2]. Subsequent papers described some of the characteristics of the LDH-elevating agent[3,4], reported a 50- to 1,000-fold rise in plasma LDH and an approximate five-fold increase in anaerobic glycolysis after 'infection' of 'virus-free' tumours with the LDH-elevating agent[5,6], and demonstrated elevated levels of other enzymes, in addition to LDH, in plasma from mice inoculated with this 'virus'[7,8].

So far, few studies on the host range of the LDH-elevating agent have been reported. Notkins *et al.*[9]

Table 1. Effect of Human Tumour Extracts on Mouse Serum LDH

Tumour	Tumour extract	No. of samples	Serum LDH (units/ml.)* Range	Mean
Carcinoma of breast	Homogenate	36	750–2,200	1,250
	Filtrate	35	700–2,000	1,100
Leiomyosarcoma of stomach	Homogenate	36	700–1,550	1,050
	Filtrate	36	700–1,800	1,100
Transitional cell carcinoma of kidney	Homogenate	34	600–1,650	1,000
	Filtrate	36	550–2,400	1,150
Melanoma of choroid	Filtrate	22	750–1,800	1,150
Controls		20	850–2,100	1,400

* One unit of LDH is defined as the enzyme activity in 1·0 ml. of serum which results in a decrease in optical density of 0·001 per 1 min at 32° C.

found no increase in serum LDH activity in rats bearing 6 different transplanted tumours. This is a report of attempts to demonstrate an LDH-elevating agent in association with human neoplasms.

Human tumours were obtained from a 35 years old female Negro, a 70 years old male Negro, a 53 years old male Caucasian, and a 69 years old male Caucasian. Histopathological examination showed these to be a carcinoma of the breast, a leiomyosarcoma of the stomach, a transitional cell carcinoma of the kidney, and a melanoma of the choroid, respectively.

Ten per cent suspensions of fresh tissue in Eagle's basal medium were homogenized for 1 min, at 8,000 r.p.m., in a Servall 'Omni-Mixer'. An aliquot of each homogenate was removed and the remaining material spun for 10 min at 5,000 r.p.m. The supernatants were then passed through 'Millipore' filters of 100 mμ pore size.

A total of 40 *C57BL/Fg* mice, approximately 3 months old, each received a 0·2-c.c. subcutaneous injection of either a homogenate or filtrate. Ten animals were not treated. Serial blood samples were obtained by tail bleeding and serums collected by routine laboratory procedures. Serum LDH activity was measured by the method of Henry *et al.*[10]; all results were corrected to 32° C. The animals were killed 15 weeks after treatment.

As shown in Table 1, the inoculation of mice with homogenates or filtrates of 4 human tumours did not induce a significant elevation in serum LDH activity. These findings suggest that an LDH-elevating agent was not associated with these neoplasms and, as such, plays no part in the elevation of serum or plasma LDH in patients with cancers[11]. They do not, however, exclude those possibilities, since there are many difficulties associated with attempts to transmit human viruses to animals.

Pertinent to this problem is the question of when serum LDH activity is increased after heterotransplantation of human tumours. Based on previous experiments with murine neoplasms[8,9,12,13], an early rise in enzyme activity prior to detectable tumour growth should not be found if human tumours are free of the agent. Further, in view of the suggestion that the LDH-elevating agent becomes associated with murine tumours during serial transplantation[8,9,12,13], it would be of interest to determine whether heterotransplants acquire the agent after repeated passage in the mouse. Although neoplasms were not observed in any of our experimental animals, the demonstration that human tumours can be transplanted to mice[14] and maintained in serial passage[15] indicates that these results can be obtained.

RADIOBIOLOGY

Effect of Thyrotropin on Nucleic Acids and Protein Contents of the Thyroid

In a previous paper[1] we reported the effect of single and repeated doses of thyrotropic hormone (TSH) on the contents of protein-bound iodine-131 ($PB^{131}I$) in whole thyroids and their subcellular fractions, 1 h after administration of $Na^{131}I$. The contents of protein, ribonucleic acids (RNA) and deoxyribonucleic acids (DNA) were analysed in thyroidal homogenates and fractions on similarly treated guinea pigs. The preliminary results of the latter investigations are reported here.

The experimental animals were male guinea pigs, weighing 200–250 g. All experiments were performed on groups, each group comprising 6 animals. A dose of TSH ('Ambinon', Organon) was given intraperitoneally once a day for 1–6 days. The animals were killed 24 h after the last injection. Different daily doses of TSH were tested, ranging from 0·2 to 2·5 I.U.

The glands of each group were pooled and homogenized in 0·44 M sucrose. The homogenate was divided into nuclear, mitochondrial, microsomal-postmicrosomal and supernatant fractions as described earlier[1].

The amounts of RNA and DNA in the homogenates and fractions were determined by Schneider's method[2]. After the extraction of nucleic acids, the protein in the precipitates was determined according to Lowry *et al.*[3].

In the controls the total RNA-content of the homogenate from six glands had a mean value of about 550 μg (Table 1). Repeated daily doses of 1·0 I.U. of TSH gave an increase of the homogenate RNA-content, which was clearly shown after one day and reached a maximum after four days' treatment (almost 2,000 μg). Administration of TSH also resulted in an increased amount of protein in the homogenate. However, this increase was less pronounced than that of RNA (Table 1). When, therefore, the

Table 1. Wet Weights and Total Amounts of RNA, DNA and Protein in Thyroid Homogenates and Fractions after Repeated Daily Doses of 1·0 I.U. of TSH. Each Value represents the Sum of a Group of Six Glands. Every Figure is a Mean Value based on at Least Three Groups

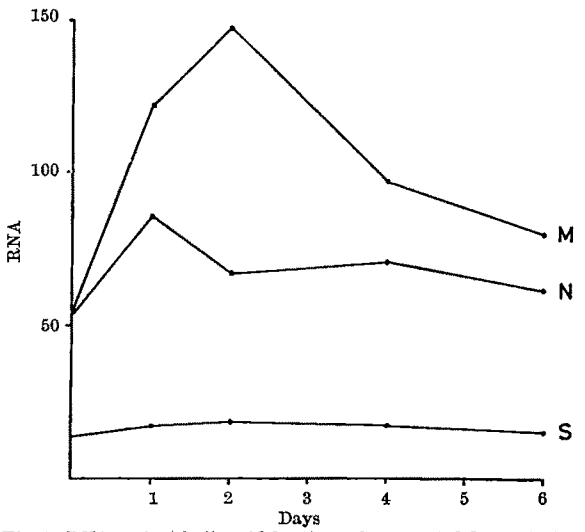

Fig. 1. RNA content in thyroid fractions after repeated doses of 1·0 I.U. of TSH. The values are expressed as μg of RNA per mg of protein in the fractions. *M*, Microsomal; *N*, nuclear ; *S*, supernatant fraction

RNA-content was calculated on protein basis it rose from 32 μg/mg of protein in the control animals to 70 μg/mg of protein after four daily doses of 1·0 I.U. of TSH. Since TSH increased the wet weight of the thyroid very rapidly, the homogenate RNA was, when calculated per mg of wet tissue, reduced after one and two days and only slightly increased after treatment with TSH for 4 days.

In the controls, the nuclear fraction had a higher content of RNA than any other fraction. It was about five times that of the microsomal fraction. However, when calculated on protein basis the nuclear and microsomal fractions showed similar values, about 50 μg/mg of protein. Administration of TSH resulted in a very rapid and marked rise in the amount of microsomal RNA, which from the second day onwards was six times that of the controls (Table 1). When calculated per mg of protein in the fraction the microsomal RNA raised from about 50 μg in the controls to about 150 μg after two days of TSH and then decreased slightly on the fourth and sixth days (Fig. 1). TSH-administration was also followed by a pronounced increase of the amount of nuclear RNA. However, it must be pointed out that the RNA-values of the nuclear fractions, both in the controls and in the TSH-treated groups, are too high owing to contamination of the nuclear fraction by unbroken cells and cytoplasmic particles.

The mitochondrial fraction contained throughout very small amounts of RNA which, judging from electron micrographs of this fraction, could be ascribed to microsomal contamination. The supernatant fraction had a fairly high RNA-content in the controls. TSH-treatment induced a slight increase after one and two days and then a reduction to, or below, control values (Table 1). The amount of supernatant protein showed fairly small fluctuations during TSH-treatment but seemed to be somewhat reduced after four days of TSH.

In the controls, the total DNA-content of the homogenate from six thyroids showed a mean value of about 1,000 μg. Most of this DNA (about 900 μg) was recovered in the nuclear fraction. One day's TSH-treatment did not significantly change the amount of nuclear fraction DNA. However, after two days' administration of TSH there was a very marked increase of nuclear DNA and after four days the amount of DNA was about twice that of the controls.

Larger and smaller doses of TSH gave results which were in principle similar to those accounted for here.

In conclusion it can be stated that administration of TSH induced in the guinea pig thyroid an increase of the RNA-content. This increase was particularly rapid and marked in the microsomal fraction and should be considered as evidence of stimulation of the protein synthesis in the gland. There was also an increased build-up of DNA which, however, was slower than that of RNA, indicating that an increase of mitotic rate is preceded by increased synthetic activity. The total protein content of the thyroid was rapidly augmented.

Further investigations, on purified fractions, are in progress.

This investigation was supported in part by research grant No. *AM* 5254–01 from the U.S. National Institutes of Health, and in part from the Swedish Medical Research Council.

BIOLOGY

Effect of Thalidomide on the Development of the Chick Embryo

THE disastrous effect of thalidomide on development of the human embryo[1] has prompted us to investigate the influence of this substance on the development of the chick embryo. Although the results given here are only preliminary, we thought it advisable to publish them in a brief communication, as they may be of interest to other workers in this field.

We injected thalidomide, suspended in 0·5 ml of a 1 per cent carboxymethyl-cellulose (CMC) gel, in doses of 1 and 5 mg per egg (White Leghorn) by the yolk sac route, a method well known in virology[2]. For each dose we used six groups of 20 eggs, group 1 being inoculated one day after the beginning of the incubation (37° C), group 2 on the second day, and so on. Another six groups of 20 eggs served as controls and were injected in the same scheme with CMC only. Three days after inoculation with the substance the eggs were candled and dead ones were discarded. These, as well as any eggs not fertilized, were excluded from all groups. From then on the eggs were candled every day, and the dead were recorded and inspected. On the eighteenth day of incubation the

Fig. 1. Embryo from egg injected one day after the beginning of incubation with 5 mg thalidomide and which expired on the twelfth day of incubation, showing deformed legs and wings grown together. Histological preparations showed that the wing bones had not grown together

remaining eggs were cooled at −20° for 2 h, to kill the embryos, and inspected.

Our results can be summarized as follows: the toxicity of thalidomide for the chick embryo in the concentrations given here was not very high. Probably there is a slight difference between 1 mg and 5 mg/egg. The survival on the eighteenth day of incubation in the six groups varied in the control series from 15/16 to 9/17 (94–53 per cent, overall 69 per cent), in the 1 mg series from 16/20 to 6/12 (80–50 per cent, overall 73 per cent) and in the 5 mg series from 12/15 to 3/10 (80–30 per cent, overall 60 per cent).

In both thalidomide series we found malformations of the legs, for example, too short or twisted. In the 1 mg series, 10 of the 23 embryos (=43 per cent) that had expired before the eighteenth day of incubation, and 9 of the 61 embryos (=15 per cent) that were alive on that day, showed these kinds of abnormalities. In the 5-mg series this was the case with 22 of the 30 embryos (=73 per cent) that had expired before the eighteenth day of incubation and with 5 of the 45 embryos (=11 per cent) that were alive on that day.

Fig. 2. Embryo from egg injected one day after the beginning of incubation with 1 mg thalidomide and which expired on the tenth day of incubation, showing only one leg and wings grown together

Fig. 3. Embryo from egg injected one day after the beginning of incubation with 1 mg thalidomide and still alive on the eighteenth day of incubation, showing growing together of the wings. Röntgen photographs showed that there was no growing together of the wing bones

Fig. 4. Left: An embryo from an egg injected on the first day of incubation with 1 mg thalidomide and still alive on the eighteenth day of incubation; right, an embryo of the same age from the control group

Fig. 5. Histological preparation of wings grown together from the embryo shown in Fig. 1. (Bismarck-brown staining after Roulet, *Methoden der Pathologischen Histologie*, Springer-Verlag, 1948)

These malformations of the legs were found in the control series only on 6 of the 26 embryos (=23 per cent) that had expired before the eighteenth day of incubation and on 0 of the 58 embryos (=0 per cent) that were alive on that day.

In group 1 we observed two embryos with only one leg in the dosage series 1 mg/egg (Fig. 2). This was not found in the control series.

In total we observed eight embryos with wings grown together or deformed, that is to say five in group 1, two in group 4 and one in group 6. There were no embryos with abnormal wings in the control series. These malformations, as well as those of the legs, were mainly found in the embryos which died before the eighteenth day of incubation.

The photographs show the main malformations which were observed, namely wings grown together, one leg, and aberrant legs.

Our preliminary impression is that thalidomide gives a higher incidence of malformations in the chick embryo, especially when given very early in the incubation period. The growing together of the wings seems very important, as we have never seen this phenomenon during more than 10 years of virological work with chick embryos.

It might be of value to include this kind of test before clinical trials of drugs are started. The chick embryo seems a rather sensitive indicator of teratogenic effects, and as there is no excretion it is easy to maintain a constant level of the substance to be tested.

We thank Prof. F. Zilliken, R. C. University, Nijmegen, for a gift of thalidomide and for his advice, Miss J. C. Sekèt, Miss N. Kors and Mrs. W. C. Bouman-ten Das for assistance, and Mr. Boeve for taking the photographs.

During the preparation of this manuscript the publication of F. Kemper[3] came to our notice. This author also observed malformations, which were, however, not further described. Growing together of the wings is not mentioned by him.

A Genus of Brackish-water Oligochæta New to Britain

During investigations into the life-cycle of *Tubifex costatus* (Claparède), 1863, in a brackish-water moat close to the shore of the River Mersey at Hale, Lancashire, a tubificid genus not so far recorded from Britain was also observed[1–4].

The worm was clearly recognizable as *Aktedrilus monospermathecus* Knöllner, 1935, from the size and shape of the animal and its chætæ, and the single spermatheca with its dorsal pore[5,6]. The worms are very thin and reach a maximum length of 1 cm, although some segments are missing posteriorly. There are very few chætæ in each bundle—a maximum of 5 in pre-clitellar bundles is much rarer than 2 or 3—and all chætæ are alike. They are all bifid crotchets with the upper teeth more or less rudimentary. The detailed structure of the male efferent ducts was not observed in this material but a careful study of whole mounts revealed that the cuticular covering of the penis was sufficiently thickened to appear as a very thin-walled penis-sheath in one specimen. This was so thin that it was distorted in whole-mount preparations and its detailed shape could not be ascertained, but it seemed to be larger than its breadth at the base and to taper distally as in *Tubifex templetoni* Southern, 1909.

Aktedrilus monospermathecus has also been recorded from the shores of Kiel Bay and Schleswig, the River Weser at Blumenthal, Vegesack, and Bremen waterworks, the Baltic in general and the Mediterranean[5–8]. The salinity preferences of the species are given as 0–18‰ and its range from 1·25–20 S‰ with a preference for 2·5–5 S‰ (ref. 8). The species was overlooked in earlier surveys of the habitat at Hale as it is very scarce; only 12 specimens were observed among 2,078 specimens of *T. costatus*. Its normal habitat is the interstitial space of sandy sea shores, but at Hale it was found in thin yellow clay overlying a thick blue-grey clay in a moat surrounding a small coppice. The moat was connected to the Mersey via an organically polluted stream which has recently been dredged and straightened to accommodate the tidal flow. The shore of the Mersey at the nearest point is a mass of foul, black mud and clay, and the nearest sandy shores are beyond Liverpool docks.

It is very probable that several other marine Tubificidae remain to be added to the British list; but many are very small and readily overlooked unless samples are sieved through a very fine mesh.

Since this note was prepared, another marine species has been recorded—(*Thalassodrilus* (*Rhyacodrilus*) *prostatus* (Knöllner), 1935—n.g. (ref. 9))—as well as *Tubifex* (*Limnodrilus*) *newaensis* (Michaelsen), 1903 (ref. 4).

Retention of Organomercury Compounds on Dressed Grain after Washing

Farmers and seed merchants may occasionally have a surplus of grain dressed with organomercury fungicide when sowing is completed. Lindström[1] has reported that more than 50 per cent of a dry formulation (containing ethylmercury chloride) was washed off grain dressed in the laboratory after shaking for 10 min with water, thus showing that washing could reduce the potential hazard of such grain if used as part of a ration to feed livestock. In contrast, less than 5 per cent of a wet dressing (methylmercury dicyandiamide formulation) was removed. Consequently, the amount of fungicide retained after washing wheat and barley, dressed commercially, has been investigated: it was found to be considerable.

In our investigations, eight 2–3-kg samples of treated wheat or barley were taken from normal large-scale dry and wet treatments; in addition, 28 kg of wheat was dressed with a methylmercury dicyandiamide formulation at request. An interval of at least four weeks elapsed between dressing and analysis.

160 g of each sample was placed in turn in a Buchner funnel and a steady stream of cold water run over the grain for 5 min; after draining for a few minutes, each sample was divided into eight aliquots of 20 g and analysed by a slightly modified procedure of that recommended by the Joint Mercury Residues Panel[2]. As controls, 160-g samples of unwashed grain were divided into 20-g aliquots and analysed. The levels of mercury found are given in Table 1.

It was found in the case of one dry formulation, based on phenylmercury acetate and ethylmercury chloride, that half the dressing could be washed off, as described by Lindström. However, in the cases of the other three dry dressings examined, only 10–15 per cent was washed off. Neither the methylmercury dicyandiamide nor the phenylmercury acetate liquid formulations were readily removed. No evidence was obtained, therefore, in the

investigation to suggest that appreciable amounts of a wet or dry organomercury seed dressing would normally be removed by washing dressed grain.

A subsidiary investigation showed that variances between 160 g samples from a seed treatment are significantly greater, but of the same order, as variances between 20-g sub-samples from the same 160-g sample. The standard errors of the means for eight 20-g sub-samples, quoted in Table I as an indication of the order of accuracy attained, are therefore slight under-estimations of the true errors for testing significance.

ENTOMOLOGY

Insecticide Resistance in the Cocoa Capsid, *Distantiella theobroma* (Dist.)

THE first large-scale trials with γ-BHC against the cocoa capsids *Sahlbergella singularis* Hagl. and *Distantiella theobroma* (Dist.) in Ghana were made in 1954[1]. The level of capsid control achieved, and the resultant crop yields of cocoa, were so outstanding that the use of this insecticide in recent years has been country-wide. Aldrin and endrin have also been used successfully and the control reported by Armstrong[2] as having been obtained with amounts of insecticide as low as ½ oz. active ingredient (a.i.) per acre is ample evidence that capsid strains, tolerant or resistant to chlorinated hydrocarbon insecticides, were unknown in Ghana in 1961. Now, however, capsids resistant to γ-BHC have been found on a plot of Amelonado cocoa at Pankese Cocoa Station, near Nkawkaw.

The plot was planted in 1956 and has since received four spray applications of γ-BHC each year, the initial spray of 4 oz. a.i. and all subsequent sprays of 1–2 oz. a.i. per acre applied in 5 gallons of water by portable, motorized mistblowers. In August 1961 it became apparent that the capsid population was building up on this plot and that the cocoa was being seriously damaged. Spraying frequency was therefore increased to once every two weeks and during December the trees were being treated individually at a rate equivalent to more than 4 oz. actual γ-BHC per acre per fortnight. However, the capsids were still not being controlled and the situation was therefore brought to the notice of the West African Cocoa Research Institute.

Using the laboratory bioassay method outlined by Armstrong[2], collections of capsids from Pankese have been compared with capsids from the Tafo area. These tests have established that the LD_{50} of γ-BHC is about 40 times higher for capsids from Pankese than it is for Tafo capsids, the decreased slope of the log. dose-probit line to 1·3 (Pankese) from 2·6 (Tafo) clearly indicating that the former have developed resistance, and not just tolerance, to γ-BHC.

A further test using aldrin, but limited in replication by the number of available capsids, has strongly indicated that the Pankese capsids are also resistant to this insecticide.

The distribution of γ-BHC-resistant capsids is thought not to be very widespread in Ghana at present, for while some cocoa at Pankese has been sprayed four times a year with γ-BHC since 1954, one of the plots in the original large-scale spraying trial being situated at this cocoa station, the other 25 sites, which also featured in the spraying trials of 1954, and which are scattered throughout the country, have similar histories of regular γ-BHC spray applications and, as yet, show no evidence of resistant strains.

The capsids at Pankese and those from Tafo, with which they were compared, were all *D. theobroma*, and it is noteworthy that this species is now the predominant cocoa capsid in Ghana, *S. singularis* being very uncommon. By contrast, in 1926, Cotterell stated that *S. singularis* was the most important cocoa pest and the population figures, given in the *Annual Reports of the West African Cocoa Research Institute*[3] and by Nicol[4], clearly show that it was once more numerous than *D. theobroma*.

S. singularis is considerably more active than *D. theobroma*, both as nymphs and adults, moving and feeding over a much larger area of the food plant[5]. The greater activity could lead to a relatively bigger pick-up of insecticide by *S. singularis* and render it more vulnerable than *D. theobroma* to toxic residues on sprayed trees. This could explain why Donald[6], using DDT, obtained 100 per cent control of *S. singularis* but not of *D. theobroma* in a trial in 1948 at Akwadum and also the recent, almost total disappearance of *S. singularis* from Ghana following the wide use of anti-capsid sprays. Thus, the sequence from about 1956 appears to be the replacement of *S. singularis* by a species less susceptible to insecticides followed by the development of insecticide resistance within that less susceptible species.

CYTOLOGY

Karotype and Revised Chromosome Number of *Amphiuma*

A REVISED chromosome number of 28 has been established for the amphibian *Amphiuma means tridactylum* Cuvier, the congo eel, from studies of both somatic and

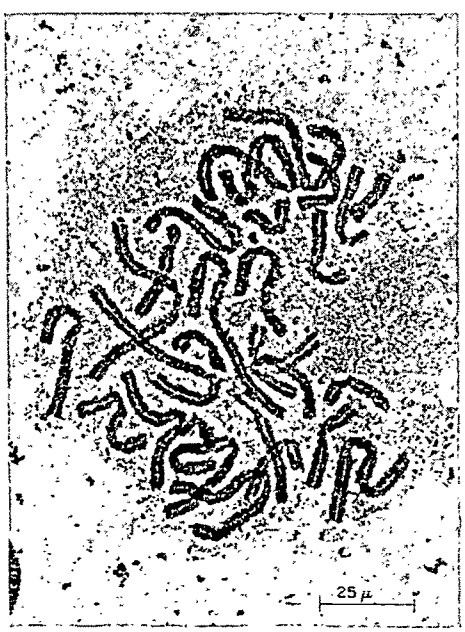

Fig. 1. Late prophase of mitosis in *Amphiuma* testis

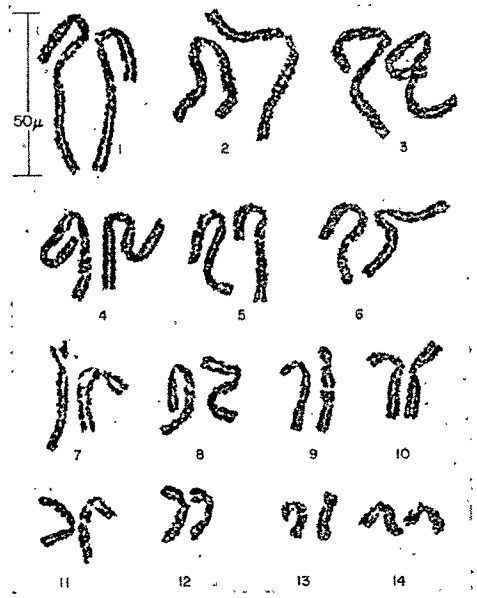

Fig. 2. Karyotype of *Amphiuma means tridactylum* constructed from Fig. 1

meiotic divisions in smears of testicular tissue. The somatic complement of 28 was clearly demonstrated in mitotic prophases and metaphases, most of which were of karyotype quality (Figs. 1 and 2). Counts derived from the various stages of meiosis, notably diakinesis (Fig. 3) and anaphase, further support the validity of the somatic count.

An examination of the karyotype (Fig. 2) reveals that the set is composed chiefly of submedian chromosomes. The largest chromosome in fully contracted metaphases has an average length of about 35μ; the smallest, a metacentric, averages about 9μ.

Heretofore, the accepted diploid number for *Amphiuma* has been 24 (refs. 1 and 2). This number is attributed to McGregor[3], who in 1899 published a study of spermatogenesis in *Amphiuma*. While McGregor did not indicate whether his material was from the two-toed or the three-toed form of *Amphiuma*, his description of an unlobed, spindle-shaped testis argues for his having studied *Amphiuma means tridactylum*[4]. It is well to note, however, that at the time of his investigation interest was in an elucidation of the process of meiosis *per se*, and not in a specific enumeration of the chromosomes.

GENETICS

Blood-typing of Indian Water Buffaloes with Reagents for Antigenic Factors of Cattle

More than eighty heritable antigenic factors have been detected on the erythrocytes (cells) of cattle by their reactions with blood-grouping reagents; the reagent being an antibody population made relatively specific for a particular factor by appropriate absorptions[1]. Using cattle reagents, it has been shown that at least nine genetic blood-group systems of cattle have their homologues in American bison, *Bison bison*[2–4], and Polish aurochs, *Bison bonasus*[5]. Water buffalo cells elicit antibodies in cattle which detect antigenic factors of three of the cattle blood-group systems[6]; suggesting a homology between the antigenic factors of cattle and water buffaloes. Naturally occurring agglutinins in the sera of cattle have been used to classify cells of Indian water buffaloes (*Bos bubalis*) into four types[7].

While on a visit to the Indian Veterinary Research Institute, Izatnagar, India, one of us (S. P. D.) tested cells of 40 water buffaloes of the Murrah breed with cattle blood typing reagents (*F*, *V*, *J*, and *Z*) prepared at Wisconsin. These reagents detected antigenic factors belonging to three blood-group systems. The blood typing, inhibition, titration and absorption tests were performed at 24 ± 2° C using standard techniques[8].

Neither the iso-immune *V* nor *Z* reagent, which detects factors at two independent blood-group loci (*F* and *Z*), reacted with any of the buffalo bloods. The heteroimmune *F* reagent produced slight hæmolysis with eight samples, but absorptions showed that these reactions were not specific. The *J* reagent (naturally occurring antibodies of normal cattle serum) reacted with six of the buffalo bloods; some of them reacted strongly (titres 128–256) and others weakly (titres 32–64). Absorption results suggested that the strong and weak reactions were due to quantitative variations in cellular *J* substance[9].

Sera from these six buffaloes with cellular *J*, and sera from 5 others lacking it as well as naturally occurring hæmolysins, were tested for inhibition of anti-*J*. The inhibition tests were done in duplicate using as test cells buffalo and cattle cells reactive with anti-*J*. The sera from the 6 buffaloes which had cellular *J* contained a soluble substance capable of inhibiting the anti-*J* reactions. Two of the 5 sera from the buffaloes that lacked cellular *J* did contain a *J*-inhibitory substance; the remaining three sera did not inhibit anti-*J*. The inhibition titres were slightly less using cattle rather than buffalo cells.

Sera from another 15 buffaloes lacking cellular *J* were tested for naturally occurring hæmolysins, and 11 sera did not contain them. One serum gave weak reactions that paralleled those of the *J* reagent in tests with cells from 10 buffaloes and 60 Hariana cattle. Sera from three other buffaloes contained antibodies reactive with most of the 62 cattle cells. Based on the blood types of these cells (obtained from the records of the Immunogenetics Laboratory, Indian Veterinary Research Institute), the reactions

of these 3 buffalo sera did not parallel those of any known cattle reagent. Absorptions with different cattle cells suggested that each serum contained a multiplicity of antibodies directed against unknown factors.

The reactivity of *F*, *V* and *Z* reagents with bison cells[2–4] and their failure to react with water buffalo cells suggest that serological relationship between water buffaloes and cattle is less close than between bison and cattle. Our results demonstrate that an antigenic system similar to *J* of cattle occurs in water buffaloes. This is another example of the ubiquity of the *J* blood-group substance. Whether or not the *J*-like substance of water buffaloes is identical with the *J* substance of cattle must await more data.

This work was supported in part by the Research Committee of the Graduate School from funds supplied by Wisconsin Alumni Research Foundation, and by a research grant (*E*-1643) from the U.S. National Institutes of Health.

We thank the Director, Indian Veterinary Research Institute, Izatnagar (U.P.), India, for use of animals and laboratory facilities.

Tests for Linkage of the Genes controlling Cattle Transferrins and Blood Groups

There are 11 genetically independent blood-group systems (loci) in cattle[1] which provide markers on perhaps a third of their chromosomes. Attempts to discover linkage between these blood-group genes and those controlling production traits have generally been unsuccessful[2]. Recent discoveries of various inherited biochemical polymorphisms such as transferrins, hæmoglobins, β-lactoglobulins, α-lactoalbumins, etc.[3], now provide additional markers for linkage investigations. This report presents the results of tests for linkage between the transferrin locus and seven of the blood-group loci.

Transferrin and blood-group data used in this analysis were obtained from Holstein–Friesian herds at Pabst Farms, Oconomowoc, Wisconsin; Emmons Blain, jun., Experimental Farm, Lake Mills, Wisconsin; and the Dairy Cattle Research Center, University of Wisconsin, Madison. Transferrin types were determined by vertical starch-gel electrophoresis using borate buffer[4]. The blood types were determined by the hæmolytic test[5] routinely used in our Immunogenetics Laboratory.

Linkage tests were performed by the sequential probability ratio test[6]. The heterozygote is distinguishable from the homozygote for transferrin type and for the *F* and *Z* blood-groups, but the genotypes of the other five blood-group loci had to be ascertained from the pedigree information. Individuals with doubtful genotypes were not used. Only families of sires heterozygous for both the transferrin (main locus) and blood-group loci (test loci) were used. The double and single backcrosses were the only informative matings. Lod scores were determined from the Z_1 tables computed by Morton[6].

Table 1 gives the accumulated lod scores from tests for linkage between the transferrin locus and each of the seven blood-group loci. The significance of the accumulated *Z* scores was tested by comparing ΣZ with $\log A$ and $\log B$. As recommended by Morton[6], $\log B = -2$ and $\log A = 3$ were taken as appropriate choices. Linkage of the order of 10 per cent recombination was excluded for blood-group loci *A*, *B*, *C* and *F*. For the *Z* and *S* loci, linkage at the level of 5 per cent recombination could be excluded. The data were not sufficient to exclude linkage with the *L* locus even at the level of 5 per cent recombination. Thus, there is yet no clear-cut linkage detectable between the blood-group loci and any other locus in cattle.

Table 1. Results of Sequential Probability Ratio Tests for Linkage between Transferrin Locus and Blood-group Loci

Blood-group locus	No. of sire families	No. of progeny	Accumulated lod scores (ΣZ) for different levels of recombination 0·05	0·10	0·20

Diploid-like Pairing in a Synthetic Decaploid *Avena*

In the course of investigations on species relationships within the genus *Avena*, a number of pentaploid hybrids derived from the cross *Avena abyssinica* Hochst. ($2n = 28$) × *A. sativa* L. (Black Mesdag) ($2n = 42$) were successfully treated with colchicine using the capping technique[1]. Thirty-six seeds were obtained from the doubled sectors of the treated pentaploid. Chromosome pairing was examined in four pentaploid hybrids and five decaploid plants. Twenty cells per plant were analysed and a short account of chromosome pairing at M_1 in both pentaploid and decaploid forms is given in Tables 1 and 2.

Table 1. Chromosome Pairing in the Pentaploid Hybrids

Hybrid No.	Mean No. of configurations per cell I	II	III	IV
4411 Cn	21·35	4·71	1·10	0·21
4412 Cn	22·25	4·14	1·00	0·25
4413 Cn	18·03	5·41	1·86	0·29
4415 Cn	19·22	4·86	1·77	0·18

On the basis of their investigations of chromosome morphology[2] and genome homology[3] in the *Avenae*, Rajhathy and Morrison concluded that there is only one common genome in the tetraploid and hexaploid species. They designated the genomic constitution of the hexaploid species as AACCDD and the tetraploids as AABB, and accordingly the expected theoretical pairing in the pentaploid would be 21 univalents and 7 bivalents. Some pairing between chromosomes of the A and B genome has been previously reported by Nishiyama[4] and the presence of multivalents in the pentaploid hybrids may be an indication of similar pairing.

According to the foregoing designation of the genomic relationships in the *Avenae*[2,3] the decaploid would be AAAABBCCDD with an expected chromosome pairing of up to a maximum of 7 quadrivalents and 21 bivalents. Lesik[5] reported 35 bivalents for a similar decaploid

(*A. abyssinica* × *A. sativa*). It will be observed, however, from Table 2 that although such complete pairing was not obtained the number of bivalents was far in excess of the theoretical expectation, and the number of multivalents less than expected.

Table 2. Chromosome Pairing in Synthetic Decaploids

Segregate No.	Chromosome No.	Mean No. of configurations per cell II	I	Multivalents per cell
352 Cx	68	31·70 ± 0·27	3·4 ± 0·43	0·35 ± 0·25
357 Cx	70	33·90 ± 0·16	1·9 ± 0·32	0·15 ± 0·08
358 Cx	69	30·75 ± 0·60	2·7 ± 0·33	1·15 ± 0·26
363 Cx	69	32·05 ± 0·34	4·15 ± 0·56	0·25 ± 0·10
370 Cx	70	33·35 ± 0·27	2·5 ± 0·32	0·25 ± 0·13

It is also interesting to note that two of the amphiploids 357 Cx and 370 Cx, both having the full decaploid complement, had a slightly higher number of bivalents per cell than the other decaploid plants investigated.

Since there is complete homology between the A genome of the tetraploid and hexaploid species[3,6] it would be expected that the chromosomes of the A genomes in the decaploid would behave like autotetraploids. Approximately 60 per cent of the chromosomes form multivalents in autotetraploids[7] and a comparable figure in the decaploid plants would normally be expected.

To account satisfactorily for the low number of multivalents found in decaploid plants one would have to postulate either the presence of a gene which suppresses multivalent formation between homologous chromosomes, or that the chromosomes of the A genome derived from the tetraploid species are slightly differentiated from those found in the hexaploid species. If the latter postulation is accepted, preferential pairing between A genome chromosomes derived from the same species would take place in the decaploids but, in the absence of the diploid complement in the pentaploid, chromosomes (AA) from tetraploid and hexaploid species were sufficiently homologous to form bivalents.

VIROLOGY

An Analysis of Adenovirus Particles and Soluble Antigens produced in the Presence of 5-Bromodeoxyuridine

The addition of 30 μg/ml. of 5-bromodeoxyuridine (BUDR) to HeLa cell cultures infected with adenovirus type 5 results in a marked inhibition of the synthesis of infectious virus, but does not prevent the development of cytopathic effect nor the formation of complement-fixing antigen[1].

The work recorded here was designed to elucidate the action of BUDR on the synthesis of each of the three soluble adenovirus antigens previously described[2,3] and to investigate the electronmicroscopical and biological properties of virus materials produced in the presence of BUDR.

A concentrated suspension of HeLa cells (approximately 2×10^7 cells in 2 ml. of maintenance medium) was inoculated with 1 ml. of trypsin-digested[4] adenovirus type 5 material containing $10^{9 \cdot 0}$ TCD_{50}/ml. After contact for 1 h at room temperature the cells were sedimented by centrifugation, washed 3 times, each in 5 ml. of Gey's solution, and resuspended in 20 ml. of maintenance medium containing 30 μg/ml. of BUDR. After incubation for 70 h at 37° C the cells were collected and extracted by the technique of Gessler, Bender and Parkinson[5] using the fluorocarbon compound 'Arcton 133' (Imperial Chemical Industries, Ltd., London) as described by Pereira and Valentine[6].

The resulting material was fractionated by chromatography on a DEAE-cellulose column as described by Klemperer and Pereira[3]. Fractions were tested by complement-fixation against homologous rabbit antiserum which revealed the presence of three distinct elution peaks corresponding closely to those of antigens *A*, *B* and *C* previously described[3], except that antigen *A* produced in the presence of BUDR was eluted at slightly lower sodium-chloride molarities than the corresponding material obtained from untreated cultures.

The fractions were also tested for hæmagglutination using 1 per cent suspensions of rat erythrocytes with and without addition of a heterotypic adenovirus antiserum (type 1) at a dilution of 1/200. The results were perfectly comparable with those obtained with materials from untreated cultures[7]; fractions corresponding to antigen *A* were devoid of hæmagglutinating activity whereas antigens *B* and *C* were both capable of causing hæmagglutination, the latter requiring for this the presence of heterotypic antiserum in the system.

Samples of each of the 3 antigens fractionated by chromatography were concentrated 10 times by dialysis against 'Carbowax'[8] and tested against homotypic rabbit antiserum by gel diffusion precipitation side by side with antigens obtained in the absence of BUDR. No difference could be detected in this way between antigens produced in the presence or absence of BUDR.

HeLa cell monolayers infected with adenovirus type 5 in the presence and absence of BUDR were examined microscopically at intervals after inoculation. Techniques used were Feulgen staining for DNA after ethanol fixation, and observation by phase-contrast after osmium tetroxide fixation. The number of altered cells was similar in the two groups, but nuclear changes proceeded more slowly in the presence of BUDR, about 70 h being needed to reach the 48 h (terminal) stage of untreated cultures. Typical DNA-containing masses formed as usual, but associated columnar protein crystals were not seen in the BUDR-treated cells.

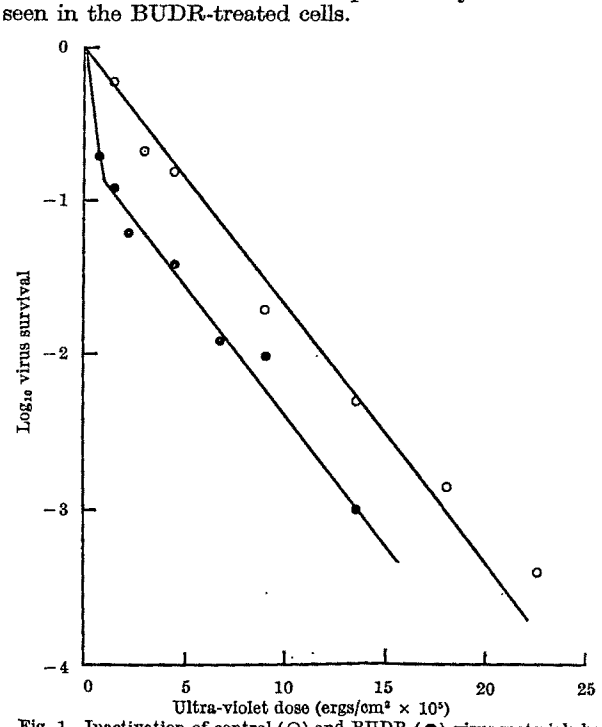

Fig. 1. Inactivation of control (○) and BUDR (●) virus materials by ultra-violet (2540 Å) radiation

Examination of the unfractionated BUDR virus material with the electron microscope revealed a relatively large number of particles with all the morphological characteristics of adenovirus particles. In preparations treated with uranyl acetate, a great majority of the particles showed a well-defined electron opaque centre surrounded by a less-opaque layer with hexagonal outline. This suggests that BUDR particles do not lack the central core of nucleic acid. Particle counts were done by the latex particle spray drop method with negative staining[9].

The infectivity titres of control and BUDR virus materials were determined by inoculating serial dilutions (0·5 $\log_{10}$ steps) into groups of 4 tubes of HeLa cells. The titration end points were read after 4 weeks' incubation with weekly fluid changes. The correlation between particle counts and infectivity titres is shown in Table 1.

Table 1. Particle Counts and Infectivity Titres of Adenovirus Type 5 from Control Cultures and from Cultures Treated with 30 μG/ML. of BUDR

Material	Particles/ml. ($\times 10^{10}$)	Infectivity doses/ml. ($\times 10^{10}$)	Particles/infectivity dose
Control	25	3·0	8
BUDR	3·5	0·0001	35,000

The low infectivity titre observed in the BUDR material could be due to residual virus from the original inoculum or, at least in part, to virus synthesized in the presence of BUDR. To test this point, we made use of the observation that incorporation of halogenated base analogues into the DNA of mammalian cells, bacteria and bacteriophages results in increased sensitivity to the inactivating action of ionizing or non-ionizing radiation[10–13]. Ultra-violet inactivation curves of control and BUDR virus materials are shown in Fig. 1. The inactivation rate of the control material is approximately constant throughout the range of ultra-violet doses included in the figure, whereas the BUDR material is at first inactivated at a rate nearly 6 times higher and afterwards at the same rate as the control preparation. From the distance between the parallel sections of the two curves it may be estimated that approximately 60 per cent of the infectivity of the BUDR material is about 6 times more sensitive to ultra-violet than the control material. From the results in Table 1, the remaining 40 per cent could be accounted for by the presence of 0·01 per cent residual virus particles from the inoculum, with normal ultra-violet sensitivity.

These results suggest that adenovirus particles containing BUDR are capable of initiating infection although the probability of this happening is considerably lower than with normal virus particles. It remains to be established whether other biological properties of the virus may be changed as a result of incorporation of BUDR.

Adsorption *in vitro* of Bovine Enteroviruses by Non-cultured Bovine and Human Tissues

The results of some recent work[1–3] have produced evidence of the importance of specific virus cell-receptor(s) (which can be demonstrated in cell or tissue homogenates by its virus infectivity binding activity) as one of the major factors controlling the susceptibility *in vitro* of cultured cells and the species susceptibility *in vivo* to human enteroviruses, or the enteroviruses tissue tropisms *in vivo* within susceptible species.

Along the lines of work suggested by these findings, an investigation of the presence of receptors for bovine enteroviruses, in various non-cultured animal and human tissues, has been undertaken.

The preliminary results of this work, regarding the adsorption *in vitro* of bovine enteroviruses to some bovine and human tissue homogenates, are summarized in this communication.

The viruses used in this work were: poliovirus type 2 (strain *MEF*-1) and the following strains of bovine enteroviruses: *LCR*-4 (ref. 4), 47/2 and 121/1 (ref. 5).

Tissue homogenates were prepared as follows: samples of various bovine organs were obtained at the abattoir from a healthy, 4-months-old calf. The materials were sliced into small fragments, washed twice with Hanks's balanced saline solution, and ground with the aid of quartz sand in a porcelain mortar. The ground tissues were suspended at 20 per cent (w/v) in Hanks's balanced saline solution and stored at −70° C. Human tissues were obtained from the autopsy of a 21-year-old woman, who died from traumatic injuries. Tissue homogenates were prepared and stored as already described.

For the examination of adsorption, a technique very similar to that reported by Kunin and Jordan[1] was used. Briefly: 0·1 ml. of a proper virus dilution was added to a 0·4-ml volume of tissue homogenate, shaken and incubated in a 37° C water bath for 2 h. At the end of this time, 4·5 ml. of Hanks's balanced saline solution was added, the preparation thoroughly mixed, and centrifuged for 10 min at 3,000 r.p.m.

The virus assay, in suitable dilutions of supernatants, was performed in duplicate monolayers of primary culture of calf kidney cells, grown in Petri dishes, using the plaque technique of Dulbecco adapted to the bovine viruses used[5].

In the experiments with poliovirus, virus assay was performed using *KB* cell monolayers.

Virus assays were performed immediately or after a few hours of storage at +4° C.

Virus controls consisted of the same amount of virus, mixed with 0·4 ml of Hanks's balanced saline solution and treated in the same manner.

In Table 1 are summarized the results of the *in vitro* adsorption studies of bovine enteroviruses to various bovine tissue homogenates.

From these results it appeas that all the surveyed tissues contain a factor actively adsorbing the viruses. Moreover, the factor in tissues, responsible for 47/2 virus adsorption, as studied in large-intestine homogenate, was heat-labile

Table 1. Adsorption of Bovine Enteroviruses by Bovine Tissue Homogenates

Bovine intestine (large)	0†
Bovine liver	0
Bovine brain	0

* Results obtained in five experiments.
† Results obtained in two experiments.

at 60° C and inactivated by treatment with ether. This finding rules out the possibility that the binding activity towards virus infectivity, found in tissue homogenates, was due to the presence of blood antibodies or of non-antibody serum inhibitors against bovine enteroviruses[6–8].

These results, in that they demonstrate a large diffusion of a factor able to bind the bovine enteroviruses infectivity in the susceptible animal host, are very similar to those obtained for poliovirus, in monkey and human organisms, by Kunin and Jordan[1].

Moreover, the bovine enteroviruses-binding factor, in respect of heat lability and ether sensibility, behaves like the human enterovirus cell-receptor.

With this in mind, attempts were made to investigate the possible identity of the bovine enteroviruses-binding factor, which probably represents a specific virus cell-receptor, with the receptor for human enteroviruses, by studying the adsorption *in vitro* of bovine enteroviruses by human tissues, and the adsorption of a human enterovirus (namely poliovirus type 2) by some bovine tissue homogenates.

The results of the adsorption study of bovine enteroviruses, strains 47/2 and 121/1, by human tissue homogenates are reported in Table 2.

These results indicate that the two bovine enteroviruses are adsorbed by human intestine as actively as by the bovine intestine, while no adsorption could be demonstrated by the other human tissues surveyed, which to some extent demonstrates the specificity of the adsorbing activity of the human intestine, and its independence from contamination with blood which on some occasions is known to possess neutralizing activity versus bovine enteroviruses[7,8].

However, from the results of the investigation of adsorption of poliovirus type 2, by human intestine and by some bovine tissues, reported in Table 3, it appears that while the human intestine homogenate presented a strong poliovirus binding activity, none of the bovine tissues tested was able to do so.

These findings demonstrate that the bovine enteroviruses cell-receptors, although they probably have to be considered of similar chemical nature, differ from the receptors for human enteroviruses in their virus-binding specificity.

VETERINARY SCIENCE

Environmental Temperature preferred by the Young Pig

Investigation has shown both the marked influence of environmental temperature on the young pig's metabolic rate and the modification of the effect of environment due to grouping new-born pigs together[1,2]. Other work has emphasized the importance of ambient temperature in relation to animal production in pig husbandry[3,4]. Complementary to measurements of metabolism and growth is the determination of the environmental temperature which is preferred by the animal, and observations have been made on young pigs for this purpose.

A simple form of thermocline was constructed. This was a hardboard enclosure 2·5 m long, 0·65 m high and 0·65 m deep, divided into four compartments, each approximately 0·6 m wide and provided with a 1-cm mesh wire floor. Each compartment had a door at the front, and each connected with the next through openings 25 cm high in the bottom of the dividing walls. Fans and heaters were mounted in an enclosed space over the chambers and were so adjusted that air was blown uniformly into the backs of the compartments; inside these the air movement did not exceed 15 cm sec^{-1}. Temperature increased progressively over the range 23°–37° C along the length of the thermocline.

38 pigs (Large White breed) were used in the experiments at various intervals between birth and 41 days; body-weight ranged from 0·90 to 9·68 kg. All the animals were feeding normally from the sow in pens in a farrowing house fitted with heated creeps. The air temperature in the farrowing house varied between 12° and 19° C during the four months in which the experiments took place. The pigs were left in the pen with the sow until 20 min before the beginning of the experiment, when they were introduced into the thermocline either singly or in groups. For observations on single pigs, the number of the door for entry into the thermocline was drawn by lot, the animal was introduced, and at 15-min intervals its position was noted through small inspection holes. After 45 min the animal was removed and returned to the sow. For observations on groups of 5 pigs, the order in which the pigs were to be introduced into the thermocline, as well as the doors of entry, were allocated at random by drawing lots. Positions were noted at 15-min intervals for a total of 60 min.

Table 1. Ambient Temperatures preferred by Young Pigs, both Singly and in Groups of Five

Age of pigs (days)	Ambient temperature (° C) 23–28	29–31	32–34	35–37	Mean ± *S.E.*
Single pigs					
< 1	1	2	5	2	32·3 ± 0·94
1–7	8	16	4	0	29·3 ± 0·44
8–41	16	33	11	6	29·8 ± 0·64
Groups					
2–7	2	3	3	0	30·1 ± 1·03
8–41	3	9	4	1	30·4 ± 0·66

In the case of pigs introduced singly, on 89 per cent of occasions the final compartment noted as occupied was already occupied after 30 min in the thermocline, that is, 15 min before the end of the observation period. For the groups, the final position had been taken up after 45 min (15 min before the end) on 72 per cent of occasions. All 5 pigs of the group were found together on 59 per cent of occasions, and in a further 23 per cent only 1 pig was separated from the group and occupying another compartment.

In Table 1 are shown the frequencies with which single pigs and groups occupied different compartments at the end of the periods of observation. The only significant difference in the results lies between single pigs less than 1 day old and those aged 1–7 days ($P = 0·01$). For the pigs older than 1 day there is no further significant change with age, either in the case of single pigs or of groups.

Rectal temperatures changed little in the time taken for observation. During the 45-min period in the thermocline the rectal temperatures of the pigs introduced singly showed a fall of 0·03 ± 0·03° C (mean and standard error, 104 observations). During their 60-min periods the pigs in groups showed a mean rise in rectal temperature of 0·07 ± 0·03° C (125 observations).

The higher preferred temperature for pigs less than 1 day old might be associated with their relatively lower metabolic rates and body temperatures, which were rising slowly following the initial fall at birth[1]. The critical temperature (that is, the environmental temperature at the lower limit of the thermoneutral zone) of pigs up to 1 week old is in the region of 34° C (ref. 1), which is above the preferred mean of approximately 30° C. Pigs older than 1 week, however, still preferred a mean temperature close to 30° C, although in the case of approximately half these pigs the critical temperature would be between 25° and 30° C (ref. 2). None the less, as the measurements of rectal temperature show, thermoregulation was satisfactorily achieved.

In these experiments the air and wall temperatures were similar, so that the chosen temperature referred to both air and radiant temperatures. In the pig farrowing house, in farming practice, the use of creep heaters means that the radiant temperature is higher than the air temperature, so that there will be a resultant operative temperature[5] different from either. The air temperatures used in the present experiments might apply as operative temperatures for litters of pigs in farrowing pens, and the observations made suggest that 30° C is the preferred short-term level for pigs more than 1 day old and 32° C for the first day after birth.

SOIL SCIENCE

Examination of the Structure of Soil Humic Acids by Pyrolysis - Gas Chromatography

Zemany[1] and Harms[2] indicated that, if the conditions of pyrolysis are maintained constant, an organic substance will decompose in a specific manner. They utilized this principle for the identification of complex organic materials by pyrolysis-infra-red, or by pyrolysis-mass spectrometry techniques. A number of workers[3–10] have also used pyrolysis-gas chromatography techniques for the identification of polymers and for elucidating the structure of non-volatile organic compounds by their characteristic chromatographic patterns. The work recorded here was designed to determine the suitability of the pyrolysis-gas chromatography technique for the identification of the components of soil organic matter, and to establish the lignin or microbial origin of soil organic matter by a comparative study of the chromatographic patterns.

Four samples of soil humic acids (extracted by sodium hydroxide by the technique suggested by Lynch[11]) obtained from widely different pedological, vegetational and climatic type soils, namely, a half-bog soil from southern Delaware (Pocomoke), a prairie soil from Illinois (Sable), a red yellow podzol from North Carolina (Cecil), and a tropical Latosol from Brazil; a sample of humic acid (extracted by sodium hydroxide) obtained from *Aspergillus niger*; and a sample of commercial lignin ('Indulin', supplied by West Virginia Paper and Pulp Co.) were used for the investigation. The pyrolysis was carried out in a stream of helium carrier gas, and the pyrolysates were fed directly into the gas chromatograph.

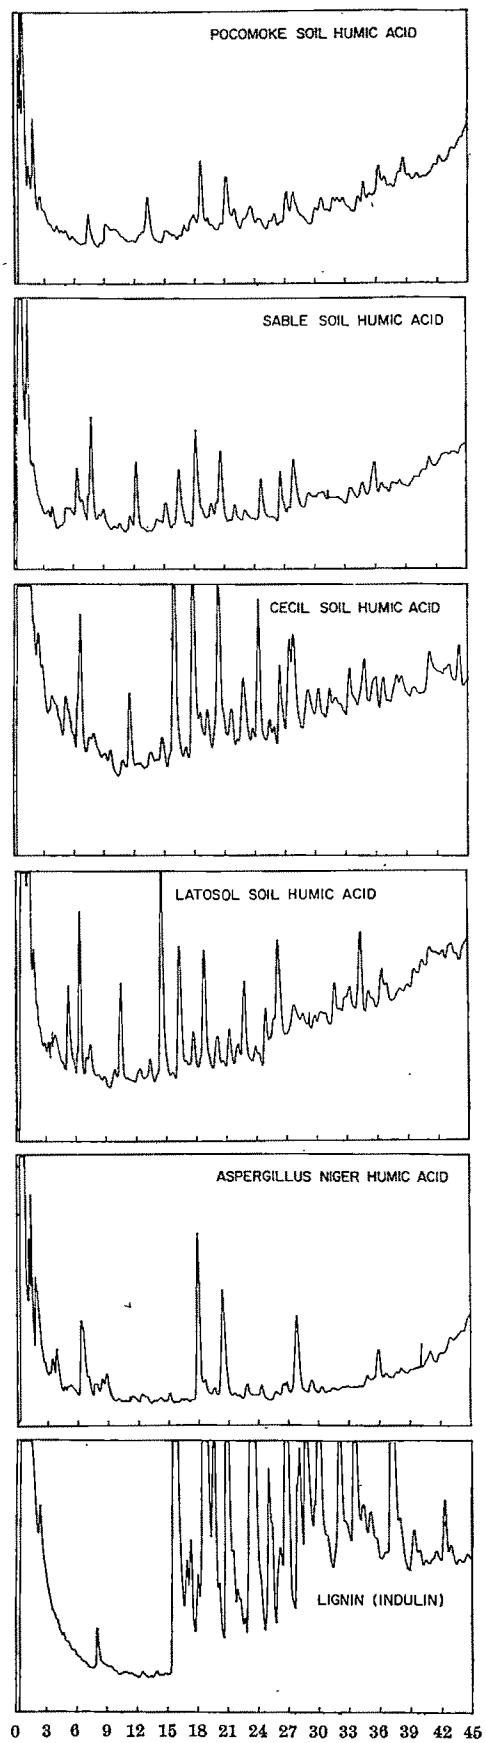

Fig. 1

Repeated experiments on the pyrolysis-gas chromatographic analysis of these six samples were conducted by varying the nature of the column, temperature of pyrolysis, sample size, nature of carrier gas and other experimental conditions. However, based on the repeated analyses, the best separation of the pyrolysates was obtained under the following experimental conditions: gas chromatograph, F. and M. Scientific Corp., U.S.A., model 609 temperature programmed instrument; column dimensions, 6 ft. × 1/8 in. (inner diam.) or 3/16 in. (outer diam.) stainless-steel coiled tube; solid support, 'Diatoports' (60–80 U.S. mesh), acid washed, base washed, siliconized; stationary phase, '*xE*-60 Nitrile Silicone' polymer (4 per cent w/w); temperatures, injections, 550° C, column: 50° C→225° C 6·4° C/min linear; carrier gas, helium at 110 ml./min; inlet pressure, 60 lb./in.^{2}: outlet pressure, atmosphere; detector, F. and M. Scientific Corp., flame ionization; recorder, Minneapolis-Honeywell Co.; 1 sec; 1/3 in./min. chart speed; sensitivity, 100 × 16; sample size, 1 mg solid (injected by F. and M. Scientific Corp. solid sample injector); analysis time, 45 min.

The chromatographic patterns obtained by the pyrolysis of the samples under aforementioned experimental conditions are shown in Fig. 1. These are representative figures based on the repeated analysis of each of the six samples. It is indicated that the pyrolysates of the Pocomoke soil humic acid contain about 10 major and 41 minor components; the pyrolysates of Sable humic acid contain about 12 major and 27 minor components; the pyrolysates of the Cecil humic acid contain about 17 major and 30 minor components; the pyrolysates of Latosol humic acid contain about 16 major and 37 minor components; the pyrolysates of *Aspergillus niger* humic acid contain about 9 major and 29 minor components; and the pyrolysates of lignin contain about 19 major and 17 minor components.

It is significant to note that the pyrolysates of lignin or *Aspergillus niger* humic acid and soil humic acid samples (Fig. 1) have quite a few common components. However, it is difficult to generalize on the quantitative aspect of the microbial or lignin origin of the soil humic acid on the basis of the present results. It is also interesting to observe that the pyrolysates of Sable humic acid and the pyrolysates of *Aspergillus niger* humic acids have about 19 similar components.

Furthermore, the present findings indicate that the pyrolysis-gas chromatography technique may provide useful results for solving the problem of the composition of soil organic matter, provided the components could be identified by infra-red, mass spectrometry, or nuclear magnetic resonance techniques.

I thank Prof. G. T. Felbeck, jun., for advice and Mr. Sam Spencer for suggestions. I am grateful also to the F. and M. Scientific Corporation, U.S.A., for providing laboratory facilities for pursuing a part of the present investigation. This communication is published with the approval of the Director of the Delaware Agricultural Experiment Station; funds for the investigation were provided by Andelot, Inc., through the University of Delaware Research Foundation.

PSYCHOLOGY

Effect of Anxiety on Real and Ideal Vocational Aspiration among Grammar School Boys

During the course of the collection of data for an investigation of certain problems related to school-leaving behaviour among fifth-form boys in a Midland's grammar school, information was obtained about their real and their ideal expectations about their own occupation achievement. This report is concerned with an analysis of relationships among these real and ideal vocational aspirations and achievement-related anxiety as measured by a modified form of the test anxiety questionnaire (TAQ)[1] which had been prepared for use within the British school system as a 15-item self-rating scale.

One hundred and thirty-one fifth-form boys were available for the investigation. Of these 131 boys, 96 provided the data reported here. The boys were assembled in two groups of approximately equal size on subsequent days during regular school hours and the TAQ was administered along with a questionnaire containing two sets of four questions about their vocational aspirations. Each question in a set differed from the other three questions only to the extent of asking for a report on vocation aspiration for a different future date. These dates were 1, 2, 5, and 10 years hence. One set of questions had to do with real vocational aspiration and asked: "What would you most like to do or be one (two, five, ten) year(s) from now?" The other set of questions had to do with ideal vocational aspiration and asked: "What would you most like to do or be one (two, five, ten) year(s) from now?" The first set of questions about real aspiration was preceded by the instruction to report ". . . what you really think you will be spending most of your time doing; what kind of job you expect to have, or what you expect to be studying in school, for example". The second set of questions having to do with ideal vocational aspiration was preceded by the request to, "Please answer the following questions in terms of what you would most like to do or be if anything were possible".

Answers to the first set of questions were taken to be an indication of the vocational achievement to which a boy actually aspired, and answers to the second set of questions were considered to be an indication of his ideal vocational aspiration. Only those boys for whom a consistency was present within each set of questions over all four questions were included for this communication. Ninety-six of the boys met this criterion.

For purposes of statistical analysis, a numerical score was assigned to each boy's vocational aspirations by comparing his stated real and ideal vocational goals with the system of social grading of occupations developed by Hall and Jones[2]. The Hall and Jones system incorporates seven social class categories and each boy's real and ideal occupational aspirations were assigned a number between one and seven based on the social class position given to the occupations by Hall and Jones. In this system, No. 1 is given to the highest social class category, No. 2 to the next, etc. The seven categories are: (1) professionally qualified and high administrative; (2) managerial and executive; (3) inspectional, supervisory and other non-manual (higher grade); (4) inspectional, supervisory and other non-manual (lower grade); (5) routine grades of non-manual work and skilled manual; (6) manual, semi-skilled; (7) manual, routine.

The TAQ scores were treated in the following manner. A frequency distribution of the TAQ scores was prepared, and the median of the distribution was determined. The range of TAQ scores was 13·0–49·0 and the median was 29·5. Scores above the median score were considered to represent high test anxiety (high TAQ) and scores below the median score were considered to be low test anxiety (low TAQ). Forty-eight boys thus formed the high TAQ group and 48 formed the low TAQ group.

To assess the relationship between achievement-related anxiety and vocational aspiration, the high TAQ and low TAQ groups were compared on the basis of the social class assignment given to their real and ideal vocational aspirations.

Table 1 presents the results of the investigation. Ideal aspiration does not differ for the two anxiety groups ($F < 1{\cdot}0$). However, within the high anxiety group real aspiration is appreciably lower than ideal aspiration at a highly significant level ($F = 11{\cdot}54$, $df = 1$ and 94, $P < 0{\cdot}01$) and real aspiration of the high TAQ group is significantly lower than the real aspiration of the low TAQ group ($F = 5{\cdot}69$, $df = 1$ and 94, $P < 0{\cdot}05$). No statistically significant difference exists between ideal and real aspiration among the low TAQ group ($F = 1{\cdot}87$, $df = 1$ and 94, $P > 0{\cdot}10$) though the difference is in the direction of a higher ideal level of vocational aspiration for this group.

Table 1. Mean Ideal and Real Levels of Vocational Aspiration of High and Low Anxiety (TAQ) Grammar School Boys
(N = 48 high and 48 low anxiety subjects)

	Vocational aspiration		
TAQ	Ideal	Real	
High	2·19	3·02	$P < 0{\cdot}01$
Low	2·10	2·42	$P > 0{\cdot}10$
	$P > 0{\cdot}10$	$P < 0{\cdot}05$	

Atkinson and Litwin[3] have argued that the TAQ provides an index of motivation to avoid failure. The higher the TAQ score the more one is motivated to avoid situations in which failure is likely or, if it is not possible to avoid completely such situations, then to modify them as much as possible in the direction of reducing the possibility of failure. Accordingly, it is suggested here that the setting of a relatively low level of real vocational aspiration by the subjects with high TAQ scores represents an attempt by them to protect themselves from failure. By setting relatively low real aspirations they increase their probability of achieving their goals and hence they reduce the probability of experiencing failure. On the other hand, when asked to state an ideal goal, one is free to set high aspiration-levels unrestricted by the possibility of experiencing failure. Because these ideal goals will not be striven for, anxiety imposes no restraints on this type of goal setting.

This work was carried out while I was a Fulbright professor of social psychology in the University of Nottingham.

Fragmentation of Patterned Targets when viewed as Prolonged After-images

When an object is viewed through some optical system which stabilizes its image on the retina a breakdown of normal vision occurs and the target may disappear[1,2]. When complex targets are viewed under these conditions disappearances may be partial[3], and the fragmentations which occur may consist of distinctly ordered, non-random segments of the original figure[4].

Most workers (for example, see refs. 5 and 6) observe, with their stabilizing apparatus, that targets disappear and reappear at short intervals when viewed for several minutes. Sometimes the whole and sometimes part of the target reappears[3]. One worker[7] suggests that all reappearances are due to a failure of the stabilization system through slippage of a contact lens, but it is difficult to explain partial reappearances in this way. Slippage would cause the entire image to shift across the retina and fall on fresh receptors. The question would be clarified if complete stabilization, without possibility of movement of the retinal image, could be achieved. It is indisputably difficult to eliminate slip of a contact lens[7] and impossible to prove that this has been done, but after-images are almost certainly stationary on the retina[8–10].

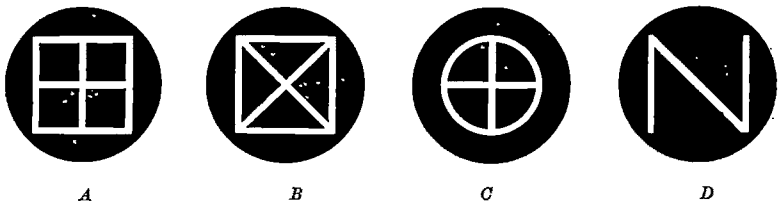

Fig. 1. Targets used in this study. The side of the square subtended 2° arc

In the present experiment we investigated the appearance of prolonged, patterned after-images. The experimental targets were drawn up on black paper out of which the outline shape of the required pattern could be cut. The black paper was backed with a sheet of tracing paper. The target was illuminated from behind by a photographic flash-bulb set in a reflector. The translucent parts of the target appeared very bright, yet evenly illuminated. With Philips '*PF*5' bulbs in a 7-in. reflector, the after-image remained visible for at least 10 min, and was sufficiently clear and positive to allow unequivocal observations to be made for at least 5 min. The duration of the flash (maker's tables) was 24 msec and the duration above half-peak intensity 12 msec. The estimated brightness of the target was about 10^6 candles m^{-2}. sec.

Five subjects were presented with the target simultaneously. Each stood about 3 m from the target, which, 10 cm in diameter, subtended an angle of approximately 2 degrees. Subjects were each instructed to fixate a particular point on the target with one eye covered. Directly the flash had occurred the experimenter switched out the lights, leaving the room in complete darkness. After 5 min observation under these conditions, subjects were asked to report on the phenomena that had occurred. Further trials were conducted after a period of at least 15 min had elapsed. Observations from trial to trial were made with alternate eyes.

The targets used were those illustrated in Fig. 1. Two trials were made with each target and all subjects reported sharp and definite after-images in each case. The general nature of the results may be summarized as follows: (*a*) After-images were of great clarity and brilliance initially, gradually losing detail but retaining sufficient positive qualities to allow reasonable observations to be made for the experimental period. (*b*) After-images faded frequently but at unpredictable intervals. Fading or disappearance was occasionally of the complete pattern, but more commonly of some part or parts of it. (*c*) There was a strong tendency for the straight lines of which a target was composed to fade as units. Typical fragmentation effects for Fig. 1*C* are illustrated in Fig. 2. (*d*) After

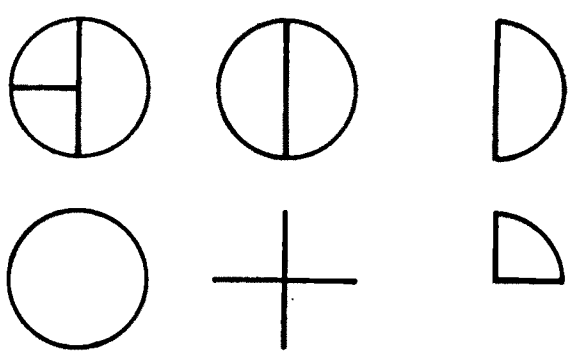

Fig. 2. Diagram showing the most frequent fragmentations observed with the after-image of Fig. 1*c*. It will be noted that entire figures are typical

fading, the image would reappear after some indefinite period of time. The nature of its reappearance was often total, that is, the image would regenerate to its normal state as a complete pattern. All subjects also reported that partial regenerations of the image might occur, and that these might feature the reappearance of single or parallel straight lines as units. (*e*) The segment of the target least likely to disappear was in the neighbourhood of the fixation point; the more peripheral the part of the pattern, the more likely it was to disappear. (*f*) After about 3 min, subjects reported a tendency for filling in of the whole of the enclosed part of the target. In due course detail was found to reappear in full. Similar results have been obtained with stabilized retinal images[5].

It has been found that, with vivid after-images of geometrical outline shapes, a range of disappearance and reappearance phenomena is experienced comparable with that reported from studies utilizing mechanical stabilizing systems. Of particular interest is the finding that disappearances may be structured, and that a large number of reappearance effects are only partial.

Yarbus[11] and Barlow[7] have suggested that a perfectly stabilized image will suffer total and lasting disappearance and that regeneration of the image must be a consequence of mechanical lens destabilization. While it is not disputed that contact lens slip will induce reappearance of an image, it now seems most likely that the partial and structured reappearances of images reported in this and other[3] studies cannot be attributed solely to such movement. Theories of retinal function that predict permanent disappearance of stabilized images will therefore need reconsideration.

This investigation was supported in whole by Public Health Service grant No. *NB.* 01233-07, from the U.S. Department of Health, Education and Welfare.

MISCELLANEOUS

Thin-layer Chromatographic Separation and Quantitative Determination of Several Free Amino-acids of Avian Liver

Thin-layer chromatographic procedures are used widely and accepted as efficient and rapid means of separating numerous organic compounds on a micro scale. The following procedure is presented to illustrate the thin-layer chromatographic separation and rapid quantitative determination of several free amino-acids of avian liver tissue.

Table 1. Recovery of Amino-Acids in a Standard Reference Solution

Amino-acid	Present	Found	Recovered
	μg/3 μl. solution		(%)
Lysine	0·30	0·30	100
Histidine	0·30	0·28	93
Arginine	0·30	0·31	103
Aspartic acid	0·30	0·32	106
Alanine	0·30	0·32	106
Valine	0·30	0·27	90
Leucines	0·30	0·28	93

Table 2. Several Free Amino-Acids of Avian Liver

Chick No.	Plate No.	No. of samples	Lysine	Histidine	Arginine	Aspartic acid	Alanine	Valine	Leucines
			← (μg/3 μl. extract) →						
20	1	6	0·41 ± 0·013*	0·29 ± 0·018	0·33 ± 0·013	0·56 ± 0·056	0·40 ± 0·039	0·28 ± 0·032	0·45 ± 0·031
20	2	6	0·43 ± 0·017	0·31 ± 0·025	0·38 ± 0·014	0·60 ± 0·049	0·41 ± 0·025	0·27 ± 0·028	0·45 ± 0·033
43	1	1	0·51	0·24	0·34	0·50	0·62	0·45	0·67
43	2	1	0·57	0·24	0·38	0·45	0·54	0·45	0·70
52	1	1	0·65	0·30	0·54	1·10	0·77	0·65	1·03
52	2	1	0·62	0·30	0·56	0·75	0·77	0·65	1·00

* Standard error of mean.

Avian liver samples are homogenized in cold distilled water (1 : 4, w/v). Free amino-acids are separated according to Awapara[1] by precipitating the proteins with absolute alcohol and separating the aqueous and organic solvent layers with chloroform.

TLC layers are prepared fresh on glass or plastic[2] plates according to standard procedures, using silica-gel *G* (Brinkmann Instruments, Great Neck, New York). When dry, the plates are placed on a heating device and warmed to 65° C and then spotted with the amino-acid solutions. A total volume of 3 μl. for each spot has been found to be appropriate. A standard reference solution of amino-acids is spotted between each of 2 unknowns. With this procedure a 20 × 20 cm plate is satisfactory for 3 standards and 6 unknowns.

Chromatographic glass tanks, of a type that can be sealed, are kept in a constant temperature atmosphere of 53° C. After the plates are spotted they are placed immediately in tanks containing a mixture of *n*-butanol-acetic acid and water (60 : 20 : 20, v/v/v). Each plate is placed in a separate tank. The solvent is allowed to run 160 mm. The plates are then removed, thoroughly dried, and re-run in the same direction under the same conditions; however, this time a 75 per cent phenol (chromatographic grade) is used as the solvent. The plates are dried again, stained with 0·25 per cent (w/v) ninhydrin (triketohydrindene hydrate) in acetone, and set in the dark for a standardized interval until the colour has developed. The chromatograms are then scanned at 525 mμ in a thin-layer chromatography densitometer (Photovolt Corp., New York).

The recovery of 7 amino-acids in a 3-μl. standard solution is shown in Table 1. Table 2 gives the content of 3-μl. extracts of several free amino-acids of avian livers. Experimental errors related to the analysis of micro quantities of biological materials are well known. Variability can be lessened and reproducibility increased if particular stress is placed on standardizing environmental conditions, preparing uniform plates, obtaining clear-cut separations and sufficient density and constancy of colour development for the particular areas to be scanned.

We thank Harry Veros for assistance. The work was supported in part by grants from the U.S. Public Health Service (E-3645) and the Photovolt Corporation, New York.

FORTHCOMING EVENTS

Tuesday, September 24

SOCIETY OF CHEMICAL INDUSTRY, PLASTICS AND POLYMER GROUP (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Mr. P. R. Thomas: "Anionic Stereospecific Polymerization of N-distributed Acrylamides and some Vinyl Ketones".

SOCIETY OF INSTRUMENT TECHNOLOGY, AUTOMATION SECTION (at Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Dr. D. B. Foster and Mr. R. I. Paterson: "Automatic Parts Handling".

Wednesday, September 25

MINERALOGICAL SOCIETY (in the Geology Department, The University, Manchester), at 2.30 p.m.—Exhibits and Scientific Papers.

BONE AND TOOTH SOCIETY (at the Institute of Orthopædics, 234 Great Portland Street, London, W.1), at 5 p.m.—Mr. L. B. H. Tarlo: "The Structure of Aspidin"; 5.30 p.m.—Mr. J. D. Currey: "Mechanical Aspects of the Structure of Bone"; 6 p.m.—Mr. J. W. Smith: "Age Changes in the Composition of Bone at the Microscopic Level".

Thursday, September 26

OIL AND COLOUR CHEMISTS' ASSOCIATION (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. M. R. Mills: "The Scientific Evaluation of Unfamiliar Vegetable Oils".

Friday, September 27

OCCAM SOCIETY (at the Northampton College of Advanced Technology, St. John Street, London, E.C.1), at 6.15 p.m.—Discussion on "Life and Body" opened by Mr. A. Healey.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER (with a good honours degree in geography, and either a higher degree or actively engaged in research leading to a higher degree and preferably previous lecturing experience) IN GEOGRAPHY at the University College of Townsville, University of Queensland, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, September 27).

RESEARCH ASSISTANT AT THE TIDAL INSTITUTE AND OBSERVATORY, for a study of methods of forecasting storm surges along the East Coast—The Registrar, The University, Liverpool (September 27).

LECTURER (with experience in teaching chemistry and preferably research in education and/or experience of industry) IN EDUCATION—The Registrar, The University, Nottingham (September 28).

SENIOR LECTURER (honours graduate with wide industrial and teaching experience, and able to undertake research) IN THEORY OF MACHINES AND MACHINE DESIGN at Kingston upon Hull College of Technology—The Chief Education Officer, Guildhall, Kingston upon Hull (September 28).

SENIOR LECTURER (preferably with a research interest in a branch of mathematical analysis) IN MATHEMATICS—The Secretary, The Royal College of Science and Technology, Glasgow (September 28).

SENIOR TECHNOLOGIST (with sound training and experience in electron microscopy (RCA, EMU 3, and Philips EM 100 available) and ultramicrotomy, and preferably with a science degree or diploma) IN THE MEDICAL RESEARCH UNIT—Prof. C. E. Lumsden, Department of Pathology, School of Medicine, The University, Leeds 2 (September 28).

ASSISTANT LECTURER IN BOTANY—The Secretary, The Queen's University, Belfast, Northern Ireland (September 30).

ASSISTANT LECTURER IN THE DEPARTMENT OF VETERINARY HYGIENE AND PREVENTIVE MEDICINE, Royal (Dick) School of Veterinary Studies—The Secretary, The University, Edinburgh (September 30).

D.S.I.R. RESEARCH FELLOW (with a Ph.D. or equivalent postgraduate experience in experimental geophysics, and preferably experience in the maintenance or development of electronic equipment) IN SEISMOLOGY IN THE DEPARTMENT OF ASTRONOMY, to undertake field and laboratory studies of seismic waves and to relate their observations to earth structure and tectonics—Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh (September 30).

GENERAL SECRETARY (with considerable administrative experience and a broad interest in natural history)—The General Secretary, Council for Nature, 41 Queen's Gate, London, S.W.7 (September 30).

LECTURER IN BIOCHEMISTRY IN THE DEPARTMENT OF CHEMISTRY in the Faculty of Science—The Registrar, The University, Manchester 13 (September 30).

LECTURERS (2) IN RADIO-ASTRONOMY IN THE DEPARTMENT OF PHYSICS of the Faculty of Science, to pursue research at the Nuffield Radio-Astronomy Laboratories, Jodrell Bank, where the Mark I 250 ft. Radio Telescope is in operation and the Mark II is under construction—The Registrar, The University, Manchester 13 (September 30).

SCIENTIST (with a good honours degree in mathematics or physics or the equivalent qualifications in statistics, and experience in the application of electronic computer techniques), to design appropriate techniques of data processing and computation in relation to research and other problems in the field of radiological protection—The Director, Radiological Protection Service, Clifton Avenue, Belmont, Sutton, Surrey (September 30).

EDUCATIONAL PSYCHOLOGIST (with an honours degree in psychology or equivalent, and preferably teaching and clinical experience)—Chief Education Officer, P.O. Box 480, Education Offices, Manchester 3 (October 4).

ASSISTANT LECTURER (specializing in mycology, and preferably with interests in other aspects of cryptogamic botany and plant pathology) IN BOTANY—The Registrar, The University, Manchester 13 (October 5).

LECTURER OR ASSISTANT LECTURER (with a good honours degree in pharmaceutical chemistry or chemistry or an equivalent qualification, and preferably experience in industrial research or medicinal chemistry) IN PHARMACY—The Registrar, The University, Manchester 13 (October 5).

ASSISTANT LECTURER (with primary interests in inorganic chemistry) IN CHEMISTRY—The Registrar, University College of North Wales, Bangor, North Wales (October 7).

LECTURER (with teaching experience and a special interest in the sociology, psychology or philosophy of education) IN EDUCATION, to assist with full-time courses for experienced practising teachers studying for the Diploma in Education—The Secretary, The University, Exeter, Devon (October 7).

HORTICULTURE GRADUATES (with an honours degree in horticulture) IN THE HORTICULTURE DIVISION—The Director, An Foras Taluntais (The Agricultural Institute), 33 Merrion Road, Dublin 4, Republic of Ireland (October 10).

LECTURERS OR SENIOR LECTURERS (2) IN THE DEPARTMENT OF PHYSICS, Makerere University College, East Africa—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (October 10).

STATISTICIAN (with an honours degree, and preferably research or related experience in the design and analysis of experimental and survey work) IN THE STATISTICS AND BIOMETRICS DEPARTMENT, An Foras Taluntais—The Director, An Foras Taluntais (The Agricultural Institute), 33 Merrion Road, Dublin 4, Republic of Ireland (October 11).

LECTURER (registered medical practitioner, preferably with some experience of hæmatology) IN THE DEPARTMENT OF MEDICINE—The Secretary, The University, Aberdeen (October 12).

VETERINARY PARASITOLOGIST (with a degree in veterinary science or its equivalent, together with a Ph.D. degree or research training of an equivalent standard and duration, and satisfactory evidence of postgraduate experience in a relevant field of parasitology) IN THE MCMASTER ANIMAL HEALTH LABORATORY, Commonwealth Scientific and Industrial Research Organization, Sydney, to participate in specific aspects of the programme of research concerned with the epidemiology and control of helminth infections of sheep—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 202/200 (October 12).

LECTURER OR ASSISTANT LECTURER IN PLANT BREEDING AND GENETICS in the Faculty of Agriculture, University of Ife, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (October 15).

SENIOR LECTURERS, LECTURERS OR ASSISTANT LECTURERS IN THE DEPARTMENT OF MATHEMATICS, University of Ife, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (October 15).

CHAIR OF SOCIOLOGY at Bedford College—The Academic Registrar, University of London, Senate House, London, W.C.1 (October 21).

PROFESSOR OF CHEMISTRY at the University College of Townsville, University of Queensland, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, October 25).

CHAIR OF PHYSICAL GEOGRAPHY—The Registrar, University College of Wales, Aberystwyth (October 31).

PROFESSOR OF ANTHROPOLOGY at Victoria University of Wellington, New Zealand—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, October 31).

SENIOR LECTURER OR LECTURER IN PHILOSOPHY in the School of General Studies, Australian National University, Canberra—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Australia, November 4).

CHAIR OF BOTANY at the University of Tasmania—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, November 11).

PLANT BREEDER (with an M.Sc. or Ph.D. degree, and preferably postgraduate experience in tobacco), for duties which will include the breeding for resistance to disease with special emphasis on aphid transmitted viruses—The Director, Tobacco Research Board of Rhodesia and Nyasaland, P.O. Box 1909, Salisbury, Southern Rhodesia (November 30).

PROFESSOR OF ELECTRONIC COMPUTATION AND DIRECTOR OF THE DIGITAL COMPUTING LABORATORY in the School of Electrical Engineering, University of New South Wales, Sydney—The Agent-General for New South Wales, 56–57 Strand, London, W.C.2; and the Appointments Section, The University of New South Wales, Post Office Box 1, Kensington, New South Wales, Australia (November 30).

ASSISTANT PROFESSOR (with postgraduate education equivalent to the Ph.D.) IN ANIMAL NUTRITION—The Head, Department of Animal Science, University of Alberta, Edmonton, Alberta, Canada (December 15).

BIOCHEMIST (preferably with some experience of simple statistics, immunology, and work with animals), to assist with routine and research work concerned with gonadotrophin and growth hormone in children—The Chemical Pathologist, The Hospital for Sick Children, Great Ormond Street, London, W.C.1.

CHEMICAL PHARMACOLOGIST or BIOCHEMIST (preferably with research experience), to investigate the mode of action of drugs currently used in the treatment of mental illness, using spectrophotofluorimetric techniques—Director of Clinical Research, Crichton Royal, Dumfries.

EXPERIMENTAL OFFICER (with distinct skill in experimental organic chemistry, and a sound knowledge of chemical theory) IN THE DEPARTMENT OF CHEMISTRY, to carry out research and development work on the controlled oxidation of aromatic compounds and of more complex materials—The Registrar, The Manchester College of Science and Technology, Sackville Street, Manchester 1.

LECTURER (with good academic qualifications and preferably with previous experience of teaching, research or industry) IN MATHEMATICS—The Academic Registrar, Loughborough College of Technology, Loughborough, Leicestershire, quoting Ref. 27/G.

MATHEMATICIAN (with research and computing experience), to work on problems of upper atmosphere dynamics—The Secretary, University College, Gower Street, London, W.C.1.

MEDICAL LABORATORY TECHNICIAN (A.I.M.L.T. or equivalent); and a SCIENTIFIC OFFICER (with a science degree), for interesting work of a specialist nature—The Administrative Officer, North London Blood Transfusion Centre, Deansbrook Road, Edgware, Middx.

ORGANIC- or BIOCHEMIST (young graduate), to join a team studying the relationship between wheat variety and growth conditions and lipid composition—The Secretary, British Baking Industries Research Association, Chorleywood, Rickmansworth, Herts.

PLANT BIOCHEMIST or BOTANIST (graduate), to undertake investigations into the fundamental and technological causes of some defects arising in fruit and vegetable products; and a BACTERIOLOGIST (graduate), to work on the microbiology of bacon with particular reference to the microbiological aspects of prepackaging in vacuum film wraps—The Director of Research, The British Food Manufacturing Industries Research Association, Randalls Road, Leatherhead, Surrey.

READER (with a good honours degree in physics and appropriate research experience) IN SOLID STATE PHYSICS (Ref. CST 63/47); and a PRINCIPAL LECTURER (with an honours degree in physics or equivalent qualification, appropriate teaching and research experience, administrative ability, and

preferably industrial experience) IN THE DEPARTMENT OF PHYSICS (Ref. CST 63/67)—The Secretary and Registrar, Bristol College of Science and Technology, Ashley Down, Bristol 7, quoting appropriate Ref. No.

SCIENTIFIC INFORMATION OFFICER (Abstractor) (with a degree in agriculture, or natural science, and able to translate from the Russian)—The Director, Commonwealth Bureau of Pastures and Field Crops, Hurley, Berkshire.

SENIOR LECTURER and a LECTURER IN THE PHYSICS DEPARTMENT—Clerk to the Governing Body, Northern Polytechnic, Holloway, London, N.7.

SENIOR TECHNICIAN or TECHNICIAN (with instrument or physics workshop experience) IN THE RADIOTHERAPY DEPARTMENT, for duties which will include physics workshop, isotope laboratory, radium and mould room work—The Group Secretary, Oldchurch Hospital, Romford, Essex, quoting Ref. 20/98.

REPORTS and other PUBLICATIONS

LETTERS TO THE EDITOR

RADIO ASTRONOMY — Page

Radiation from Jupiter at 178 Mc/s.—J. F. R. Gower 1273

GEOPHYSICS

Magnetotelluric and Very Low Frequency Signatures from Small High-Altitude Nuclear Explosions.—R. A. Santirocco and D. G. Parker . . . 1273
Detection of Scattering Layers in the Upper Atmosphere (60–140 km) by Optical Radar.—Prof. G. Fiocco and Prof. L. D. Smullin 1275
Gravity Measurements over the Rhum Tertiary Plutonic Complex.—R. McQuillin and Dr. J. Tuson 1276

GEOLOGY

Isostatic Recovery in Scotland.—Prof. H. Godwin, F.R.S.; Dr. D. F. W. Baden-Powell . . . 1277

MINERALOGY

Strength and Structure of Flint.—R. K. Iler . . 1278

PHYSICS

A Ready Method for finding Eccentric Dipole Time.—K. D. Cole and G. V. Simonow 1279
Electrical Conductivity of Ammonium Perchlorate.—Dr. Philip Zirkind and Dr. Eli S. Freeman . . 1280
Spectra of Giant Pulses from a Ruby Laser.—Dr. D. J. Bradley, A. W. DeSilva, D. E. Evans and M. J. Forrest 1281

ENGINEERING

Reversed Plastic Flow during the Unloading of a Spherical Indenter.—K. L. Johnson . . . 1282

METALLURGY

Crystal Growth of Titanium.—Sakae Takeuchi, Hideji Suzuki and Osamu Watanabe 1283
Liquid Metal Heat Transfer in Packed Beds.—N. Standish 1284
Twinning at 77° K of 'Flash-annealed' Niobium.—Mlle. A. Fourdeux and Dr. A. Wronski . . . 1284

RADIOCHEMISTRY

A Simple Preparation of 5-Iodo-2′-deoxyuridine labelled with Iodine-131 using Iodine Monochloride.—A. D. Brownstone 1285

CHEMISTRY

Occurrence in Egg Yolk of Plasmalogenic Triglycerides.—Prof. M. Proštenik and M. Popović . . . 1285
Electrical Conductivity of Solutions of Aluminium (III), Gallium (III) and Indium (III) Iodides in Alkyl Iodides.—A. Halpern and A. Polaczek . . . 1286
Effect of Electron Donors on the Isotopic Exchange between Aluminium (III), Gallium (III) and Indium (III) Iodides and Alkyl Iodides.—A. Polaczek and A. Halpern 1286
Preparation of Aluminium Arsenide by a Vapour Phase Transport Reaction.—D. E. Bolger and B. E. Barry 1287
Characteristics of Benzylic Carbanions.—Dr. T. J. Wallace, J. E. Hofmann and A. Schriesheim . . 1287
Preservation of Thin-layer Chromatograms.—Dr. C. S. Knight 1288

BIOPHYSICS

Separation of Sieves with Microscopic Pore Diameters.—Wm. H. Dobelle and Ralph K. Witt . . . 1288

BIOCHEMISTRY

Origin of Norepinephrine in the Heart.—Dr. Irwin J. Kopin and Edna K. Gordon 1289
Mucoid isolated from Bovine Red Cells exhibiting Strong *Pneumococcus* Type XIV Cross-reactivity.—Dr. G. Uhlenbruck and Dr. M. Krüpe . . . 1289
Sedimentation Constant–Molecular Weight Relation of Ribosomes.—Akira Inouye, Yoshiya Shinagawa and Sumio Masumura 1290
Maltose in Red Clover (*Trifolium pratense*) Leaves.—Dr. R. W. Bailey 1291
Carbohydrases of the Rumen Oligotrich *Eremoplastron bovis*.—Dr. R. W. Bailey and R. T. J. Clarke . 1291
Isolation of Alkaloids using Ultrasonic Energy.—Prof. Augustus E. DeMaggio, John A. Lott and Robert J. Terraughty 1292

PHYSIOLOGY — Page

Sodium and Water Transport across Isolated Intestine of a Marine Teleost.—C. R. House and K. Green . 1293
Transient Responses of Purkinje Fibres to Non-uniform Currents.—A. E. Hall and Dr. D. Noble . . 1294
Substance *P* Content and Effect on Capillary Permeability of Extract of Various Parts of Human Brain.—Prof. F. Lembeck and K. Starke . . 1295
Reduction by Chlorpromazine of Pylorus-ligation Ulcers in the Rat.—Roy N. Tiede, Carl J. Pfeiffer and George H. Gass 1296

ANATOMY

Centrifugal Fibres in the Lateral Olfactory Tract.—T. P. S. Powell and Dr. W. M. Cowan . . . 1296

HÆMATOLOGY

Occurrence of Hæmoglobin H in Leukæmia.—Dr. G. H. Beaven, B. L. Stevens, N. Dance and J. C. White . 1297

PHARMACOLOGY

Thyroid-adrenocortical Antagonism and Histamine Metabolism.—P. S. J. Spencer and G. B. West . 1298

PATHOLOGY

Rapid Liver Tumour Induction by Concerted Action of *N*-Hydroxy-2-acetamidofluorene and Hormonal Stimulation.—Dr. S. R. Pai, Dr. R. S. Yamamoto and Dr. J. H. Weisburger 1299
Carcinogenicity of Preheated Fats.—Dr. R. S. D. Zaldívar 1300

RADIOBIOLOGY

Induction of Mutations and Killing of Cells in Irradiated Spermatogonia of *Drosophila*.—Per Oftedal 1301

BIOLOGY

Accumulation of Amino-acids in Plant Cell Tissue Cultures.—R. L. Wickremasinghe, T. Swain and J. L. Goldstein 1302
Intermittent Germination of *Capsella*.—Sir Edward Salisbury, C.B.E., F.R.S. 1303
Electron Paramagnetic Resonance in Non-irradiated Bone.—Prof. Robert O. Becker 1304
A Graphical Method for comparing the Ratio of the Number of Cells to the Volume of Medium in Tissue Culture Containers of Various Sizes.—Dr. N. M. Larin and B. Roberts 1305
Effect of Electrostatic Fields on Cell Mitosis.—Dr. L. Bozóky, Dr. Gy. Kiszely, Dr. T. A. Hoffmann and J. Ladik 1306
Incidence, Size and Shape of Meta-cortex Fibres in Wool.—J. Marcet and W. J. Onions 1306

CYTOLOGY

An Effect of Thyroxin on the Fine Structure of the Rat Liver Cell.—Dr. G. E. Paget and J. M. Thorp . 1307

MICROBIOLOGY

Specificity of the Solute Requirement by Marine Bacteria on Primary Isolation from Sea-water.—Prof. Darrell Pratt 1308
Effect of *Mycobacterium tuberculosis H37Rv* grown *in vivo* (*LH37Rv*) on Ehrlich Carcinoma Ascites Cells.—Dr. M. Artman and A. Bekierkunst . . . 1308

VIROLOGY

Murine Infection with Reovirus Type 3 and the Runting Syndrome.—Prof. N. F. Stanley and P. J. Leak 1309
Incorporation of 5-Iodo-2′-deoxyuridine into the Deoxyribonucleic Acid of Vaccinia Virus.—William H. Prusoff, Y. S. Bakhle and Prof. J. F. McCrea . 1310

SOIL SCIENCE

Age of the Youngest Hydrated Halloysite in Kyushu.—Shigenori Aomine and Nobufumi Miyauchi . 1311

PSYCHOLOGY

Ipsilateral Confusion in 2-Choice and 4-Choice Responses with the Hands and Feet.—K. W. Blyth . 1312

CHAPMAN & HALL

COLORIMETRIC ANALYSIS

Volume Two: Metals, Acid Radicles and Organic Substances

NOEL L. ALLPORT & J. E. BROCKSOPP *SECOND EDITION*

In this new edition it was not possible to compress the subject within the limits of the single volume in which the work was first published. Publication of the present volume, therefore, completes a radically revised and expanded second edition. A great deal of the original material has been retained, but only where the procedures are sound by modern standards.

Illus. 60*s. net*

CHROMATOGRAPHIC METHODS

R. STOCK & C. B. F. RICE

An account of chromatographic techniques in current use, with the emphasis on the most important methods: paper and gas chromatography. The treatment is dictated by practical considerations and details are given of some model experiments based on the authors' own experience.

Illus. 40*s. net*

ENCYCLOPEDIA OF X-RAYS AND GAMMA RAYS

Edited by G. L. CLARK *A REINHOLD BOOK*

A total of 300 specialists have written more than 350 articles under the editorship of a professor who has spent more than forty years in the radiation field and is acknowledged as an international authority on X-rays. The contributors are from all parts of the world, and describe all areas of this vast subject.

THE NUCLEAR TEST BAN

IT is scarcely twenty years since a world, already torn apart by war, learnt from the name of a Japanese city—Hiroshima—that a major scientific discovery had created for the future a peril far greater than any that had ever been known. The late Niels Bohr, whose discoveries in the field of atomic physics had done much to provide the theoretical basis for the war-time development of atomic energy, had been in no doubts when he prophesied in a secret document penned a year or two before this happened that the inevitable emergence of nuclear weapons would "completely change all future conditions of warfare". This proposition has been at the heart of all the attempts that have been made since then to bring nuclear energy, and particularly its military applications, under international control. The successful conclusion of the recent test-ban treaty, for which the world owes much to the patient efforts of the British Prime Minister, thus provides a useful moment both to review what has gone before, and to appraise the situation which has resulted.

Over the past twenty years many eminent scientists, both inside and outside Government machines, have engaged themselves in the struggle to achieve the kind of international understanding of which the test ban is the most important sign so far. This they did because they were in a unique position to appreciate the completely new qualitative look, as opposed to quantitative transformation, which nuclear weapons had imposed on warfare. The task which they set themselves was to convince their military and political colleagues that the emergence of nuclear weapons implied nothing less than this, and that their existence threatened to outmode warfare as an instrument of major national policy. As they struggled to put this point over, usually against a tide of conventional and unheeding military thought, and often opposed by the pressure of powerful interests, their own sense of social and political responsibility inevitably took on a new meaning, and just as inevitably divided. The struggle became chaotic, and bitter differences of scientific opinion, stemming to some extent from personal animosities, helped to confuse the main issues.

The first serious effort to bring about the international control of nuclear weapons was the 1946 U.S. Baruch Plan. Its failure accelerated, and then made public, the deep divisions of opinion which were growing within the American scientific community about the way weapon technology should develop. The story is too well known to need re-telling in detail. After the U.S.S.R. had carried out its first atom bomb test, in 1949, an intense debate opened about the wisdom of proceeding with the development of an 'H-bomb'. The decision to go ahead in due course led to the removal from the nuclear stage of Dr. Robert Oppenheimer, wartime director of the U.S. Atom Bomb project, and the emergence and dominance of Dr. Edward Teller. The story of their conflict remains one of the major dramas of the post-war scientific era.

The ensuing race to perfect fusion weapons of high yield, a race in which the United Kingdom played a prominent part, inevitably increased world fears, and at the same time strengthened the intensity of the debate about the advisability of checking the proliferation of nuclear weapons. World-wide alarm about radioactive fall-out mounted rapidly after 1954, when the first big series of U.S. hydrogen bomb tests began, and had reached such proportions by 1958 that both the West and East found themselves compelled to convene a conference of scientific experts to examine the technical feasibility of monitoring an agreement to discontinue nuclear tests, in whatever medium they were carried out.

Thus little more than a decade after the first atom bomb had been used, and at a time when the arms race was accelerating fast in the pursuit of the doctrine of massive retaliation, governmental and non-governmental scientists were again brought together—this time in Geneva—to see whether a first step could be taken to bring the nuclear weapon under effective control. It was to the scientists that the political leaders of the nuclear powers, as well as the world at large, looked once again for the formulation of measures which might help reduce the dangers of world-wide destruction.

The 1958 Conference of Experts was scarcely a meeting of minds. While the Western scientific delegations urged the need to separate scientific analysis from political action, in the Russian view science, even though 'objective' in its methods, had to be subordinated to national requirements; discussion of technical issues was meaningless in the absence of political direction. With this difference of outlook, it was not surprising that, while it proved fairly easy to reach agreed conclusions about the capabilities of various methods for detecting and identifying nuclear explosions, it was all but impossible to formulate an agreed report for an integrated control system. Nevertheless, after nearly two months of debate, a joint report was produced, and was generally welcomed as representing a new and hopeful advance towards the solution of the technical and general problem of controlling what was, in effect, a major measure of disarmament.

Armed with this agreement, the nuclear powers almost immediately embarked on political negotiations which had as their aim an agreement for the cessation of nuclear weapon tests under effective international control. These negotiations have proved far more protracted than many hoped at the start. Since 1958 they have engaged the attention of more and more countries. The United Nations became their forum, while at the same time bilateral talks, both official and unofficial, continued to

be held whenever propitious. At every turn new considerations, direct and indirect, political and military, emerged to colour the issue. But finally, through what has proved both a process of national education, and a search for national advantage and security, the nations have taken a first step towards a safer world.

Although, during the more recent phase of the story, there may have been pressure from the scientists and military of both sides for new rounds of tests, it is tempting to believe that a step towards a ban could have been taken sooner if scientific and political considerations had been better separated than they appear to have been over the years since the debate began. The scientist's job was to define methods by which any nation which was party to a treaty could feel confident that no other nation was violating the agreement, and so gaining some conceivable military advantage. He had to elaborate methods of detecting tests whether carried out in the atmosphere, beyond the atmosphere, under water, or underground. He had to show how nuclear explosions could be both detected and differentiated from natural disturbances occurring at a distance. As is well known from the public record of the protracted discussions, the scientists concerned did not always interpret their task in the same way, particularly when it came to the discussion of underground tests. Taking a sophisticated view about what kind of developments in seismology were likely, as well as a practical view about the technical difficulties and costs of cheating, some felt that what the politicians wanted could soon be achieved. Others became concerned to show that, in spite of all possible seismic developments, cheating would always be possible, and to prove their point were only too ready to devise theoretical schemes of fanciful proportions which would permit of cheating. This debate could never have been settled by purely scientific considerations. At no time could scientists have guaranteed to detect at a distance every small underground nuclear explosion, or to distinguish between such an explosion and a natural earthquake or a chemical explosion of comparable size.

Had the political environment become favourable before the present year, it would have long ago been possible for the politician to remove the discussion from the scientific arena. The scientist could be expected to isolate and evaluate the technical problems concerned; but in the last analysis he could never assume the politician's responsibility for making the final political judgement, taking into account all the scientific facts which were available. But be this as it may, the world has, at long last, achieved an agreement to ban tests of nuclear weapons everywhere except underground; and even such tests are precluded if venting leads to radioactive contamination which affects countries other than the one carrying out the test.

If what has been achieved is less than some hoped for, it is nevertheless of major significance. The treaty immediately lessens public anxiety about the deleterious biological effects of contamination of the atmosphere with radioactive debris. It will also both slow down and impede further nuclear weapon development by the existing nuclear powers, and, both directly and indirectly, will inevitably impede, if not prevent, the proliferation of nuclear weapons, particularly among all those nations already party to the treaty. For the treaty specifically enjoins its signatories to: (*a*) prohibit, to prevent, and not to carry out any nuclear weapon test explosion, or any other nuclear explosion, at any place under their jurisdiction (within the prescribed environments); (*b*) refrain from causing, encouraging, or in any way participating in, the carrying out of any nuclear weapon test explosion, or any other nuclear explosion, anywhere which would take place in any of the prescribed environments.

It would, of course, have been better to have achieved the original objective of a comprehensive treaty which took in underground tests as well as those catered for in the present agreement. For although the present treaty calls for a continuation of negotiations for the discontinuance of all nuclear test explosions, it does leave open the possibility of further nuclear weapon development through experiments carried out underground. The extent to which this is either possible or useful has been very fully indicated in open debate in the U.S. Senate Committee Hearings which provided the prelude to the debate in the Senate which has just ended in the decision to ratify. But whatever the answer here, the treaty, nevertheless, contributes significantly to a reduction in international tension, and at the same time opens the door for a further move towards disarmament. As Walter Lipmann has written: "The treaty takes out of the race of armaments most of the feverish gamble for supremacy which unlimited testing invites".

The case for the agreement has been generally upheld both for this reason and because of the belief that its overall advantages outweigh whatever technical risks there may be of cheating and of any consequent military exploitation. Opposition to the treaty in the United States has focused on the possibility of a Soviet breakthrough in the field of anti-missile defence, and on the possibility that the Russians, by testing underground, might redress the balance of advantage—given this can be measured at all—which the West is at present thought to have in low-yield tactical nuclear weapons. This school of thought has been spurred on by Dr. Teller, and in it may be included many who are opposed to any attempt to achieve a real measure of disarmament. Indeed, some of President Kennedy's remarks at a recent press conference could be taken to imply that Dr. Teller was scarcely likely to be satisfied by any agreement which banned tests.

Against the kind of opposition which has been put up, it has been authoritatively maintained that the most difficult problems to be solved in developing an anti-ballistic missile system are in themselves non-nuclear and can be vigorously explored without nuclear testing. The concept of the United States forging ahead of the U.S.S.R. in anti-missile development, if all are allowed to engage in unlimited atmospheric testing, has also been described by Walter Lipmann as "a romantic form of self-deception. . . . Dr. Teller's promise that American scientists will be able to do what Soviet scientists will not be able to do is not a scientific judgement. It is a reckless pseudo-patriotic gamble on the inherent superiority of American over Russian scientists".

So far as tactical nuclear weapons are concerned, it has been cogently argued, both on scientific and military grounds, that the continuance of underground tests could never upset the deterrent balance between the major nuclear powers; this is firmly based on mutual threats of 'strategic' destruction of each other's homelands. Arguments to the contrary are bedevilled by confusions about what is 'tactical' and what is 'strategic'; too often do they discount the fact that the philosophy of limited or tactical nuclear warfare only makes sense for the

winning side, and that the loser might prefer to carry others with him into 'strategic' destruction; they ignore the fact that the physical damage caused by even a single nuclear explosion, however impressive that damage may be, is vastly augmented in significance by the psychological impact in terms of human reaction.

Now that the U.S. Senate has ratified the treaty, the world has an opportunity to exploit the political climate the agreement has helped to generate, and to press on to the next steps in disarmament. Among the possibilities being discussed are the reciprocal establishment of fixed observation posts at important rail and road junctions, harbours and airfields in NATO/Warsaw Pact countries, including the Soviet Union, so as to give warning of the mobilization of forces and surprise attacks; a non-aggression pact; the freezing of defence budgets; and the extension of the present test-ban treaty to include the underground environment. It is for the politicians to decide which step comes first, and how it is to be negotiated. In the meantime, scientists, both independent and in government employment, will continue to explore the most fruitful fields for future agreement and to isolate and evaluate relevant technical issues. It has recently been announced that a continuing study-group of American and Russian scientists has been set up to do precisely this, and it is hoped that it will not be long before British scientists are included. For of one thing we can be sure, scientists are unlikely now to disengage from the struggle to enhance the physical security of the world in which we all live, and which was brought into greater peril by the applications of their nuclear discoveries.

TO BE TASTED, NOT SWALLOWED

Problèmes Actuels d'Ophthalmologie, II

Dirigé par E. B. Streiff. (Bibliotheca Ophthalmologica, Fasc. 60.) Pp. x+218. (Basle and New York: S. Karger, 1962.) 50 Swiss francs.

Advances in Ophthalmology

Vol. 13. Edited by E. B. Streiff. (Bibliotheca Ophthalmologica, Additamenta ad Ophthalmologica, Fasc. 62.) Pp. vi+265. (Basle and New York: S. Karger, 1963.) 60 Sw. francs.

Physiology of the Eye

By Hugh Davson. Pp. vii+492. (London: J. and A. Churchill Ltd., 1963, second edition.) 65*s*.

THIS trefoil illustrates three types of writing. *Modern Problems in Ophthalmology* shows all the ardour and enthusiasm of writers who present their own work; indeed, so original are these papers that there are no references to other people's writings. *Advances in Ophthalmology* contains reviews, characterized by the eclecticism that many reviewers are bound, and some choose, to follow. The third volume, a text-book, combines the foregoing qualities and laces them with simplifications which run through the whole gamut from facilitation in presentation to undeliberate misrepresentation. The first volume contains matter discussed at an international colloquium on photocoagulation held in Lausanne as long ago as September 1959. The delay between the original presentation of the papers and the appearance of this volume is deplorable, must be disappointing to the authors, and, in view of the strides which lasers are making in this field, galling to the publishers. None the less, the book is extremely valuable to the clinician, for the colloquium assembled all the leading exponents of the art of photocoagulation. This interesting technique is discussed in all its detail, both from the technical and the clinical points of view. It is significant that its inventor, Meyer-Schwickerath, should be among those emphasizing its limitations with more vehemence than some of his followers are inclined to do. The problems covered include the use of photocoagulation in lesions of the more accessible parts of the eye, such as the lids, the conjunctiva, the cornea, and the iris. There is also a discussion of the prophylactic treatment in the case of retinal detachment together with a discussion on the value of injections of vitreous. The treatment of Eales's disease with diathermy and photocoagulation is also dealt with, as is the problem of tumours of the retina and the choroid. As Ten Doesschate pointed out, this was the first occasion on which an international conference chose to discuss the conservative treatment of these tumours. The production of the volume, a valuable addition to the clinical literature on photocoagulation, is excellent.

Advances in Ophthalmology is in its thirteenth year and has succeeded in living up to the high standard set by the preceding volumes. The reviews are of varied import. A lively article by Streiff on the gerontology and geriatrics of the fundus oculi deals not only with the incident literature but also with the author's own clinical findings. The informed reader will probably find the latter of more interest than the former, in part perhaps not quite as critical as this difficult subject demands. Nowhere is this clearer than in the discussion of the changes in retinal function, where the author failed to consider changes occurring in the rest of the eye. It may be mentioned parenthetically that the French title *Gérontologie et gériatrie* does not convey the expected distinction in English, for gerontology is the science of age and geriatrics the care for the aged, whereas Streiff uses these terms to differentiate physiological from pathological senile changes. Malbran and Dodds describe operative and post-operative eye complications in retinal detachments, a paper which forms a useful, though not exhaustive, introduction to a collection of puzzling conditions. Maeder's review of the literature on the pupil shows eclecticism at a premium; papers published, for example, in physiological or optical journals are largely missed. The volume concludes with a general review on trachoma by Bietti and Vozza which is very well documented and forms an invaluable introduction to the work and literature on this disease, the research into which has made such striking progress during the last few years.

Four classes of reader may turn to Davson's *Physiology of the Eye*: research workers, students, teachers, and examiners. The first will find the book a useful introduction to vision, the physiology of the eye, also to the elements of visual optics. They will frequently be referred to the four volumes of *The Eye* and learn that this book shares many of their advantages and also disadvantages. Students, who form the major but not the most important part of the audience of this book, will think it useful, and the first hundred pages or so positively enjoyable. They will find it greatly expanded in comparison with the first edition. A few passages—as must be true of any text-book—will leave them somewhat bewildered; for example, regarding the difficult question of false torsion they will be scarcely any wiser after than before reading the section attempting to explain it and they may well query Fig. 142, for it passeth understanding. But they will be overjoyed by the large number of good illustrations, conspicuous by their paucity only in the chapter on the protective mechanism of the eye. Teachers will want to use the book with as much avidity as circumspection. They will realize that Dr. Davson has written these pages in great awe of authority, which makes him often judicially

cautious in expressing personal views, a circumstance, by the way, that medical students will find unusual but which ought to do them a lot of good. Teachers will also probably find the anatomical parts explained with greater lucidity than the more recondite problems of visual physiology where, as is inevitable in as catholic an approach as Davson has succeeded in following, a few inconsistencies have crept in. Examiners, though the smallest but perhaps the most important group of people who may turn to this book, will be in a quandary. If they are omniscient—and they would scarcely be examiners if they were not—they will realize that this book contains heresies, and that in some respects it is already out of date. Are they going to mark a student's performance on his ability to provide answers to the questions they have set or on his ability to reproduce the gospel according to this book? They will allow their judgment to be governed by the book in matters which are well established or beyond dispute, but would be wise to tolerate an unexpected answer on the student's part if this appears reasonable.

R. A. Weale

PORPHYRIN DISORDERS

Diseases of Porphyrin Metabolism

By A. Goldberg and Prof. C. Rimington. (A Monograph in the Bannerstone Division of American Lectures in Living Chemistry.) Pp. xvi+231. (Springfield, Ill.: Charles C. Thomas, 1962.) 9.75 dollars.

DISCOVERIES in pure science usually precede their developments in applied science, and it is refreshing to encounter a topic in which both forms of science have in turn contributed equally to knowledge. This is especially true of the development of our understanding of porphyrin metabolism. Towards the end of the nineteenth century and the beginning of this, Garrod and other clinicians in Britain and in Germany observed red pigments in the urine and fæces of patients with certain diseases. The first scientific advances were made by Fischer and his colleagues, who investigated the chemistry of these porphyrin pigments and established their chemical structures and synthesized them. In 1935 Waldenstrom, a clinician, demonstrated the presence of porphobilinogen (PBG), a colourless precursor of porphyrins, in the urine of subjects with acute intermittent porphyria. This condition was thus clearly distinguished from congenital or photosensitive porphyria in which large amounts of preformed porphyrins were excreted. In 1946, Shemin and Rittenberg showed that, in the rat and in normal man, glycine was specifically incorporated into the protoporphyrin of the circulating hæmoglobin. Subsequent work by British and American groups showed that the uroporphyrin and coproporphyrin of Series I excreted by patients with congenital porphyria were synthesized from the same precursor as the protoporphyrin of the circulating hæm, even though this pigment belonged to Series III. Acetate was then found to be incorporated into hæm, and the brilliant work of Shemin involving the chemical degradation of the labelled protoporphyrin isolated from hæmoglobin after feeding ^{14}C- and ^{15}N-labelled glycine and ^{14}C-acetic acid showed the origins of all the atoms of this compound. This worker suggested that the protoporphyrin was synthesized by way of a monopyrrolic precursor formed by condensation of two molecules of an asymmetric four-carbon compound derived from glycine and acetic acid. Four molecules of the monopyrrole condensed to yield uroporphyrinogen from which coproporphyrinogen and protoporphyrin were afterwards formed. The monopyrrolic precursor was thought to be porphobilinogen and its isolation by Westall was a triumph for a clinical chemical department; progress then had to await the establishment of its structure by Cookson and Rimington and its synthesis by Jackson and Macdonald. This was soon followed by the demonstration of the enzymatic synthesis of porphobilinogen from succinyl coenzyme A and glycine via δ-aminolaevulic acid (ALA). Since then there have been many investigations on the mechanism of specific formation under physiological conditions of Series III porphyrins.

The disturbances of this biosynthetic pathway responsible for the various clinical disorders of porphyrin metabolism are now subjects of intensive study in a number of laboratories throughout the world. Although many details remain to be filled in, our knowledge has progressed considerably and has supported Garrod's concept that these inborn errors of metabolism were due to enzymatic deficiencies. The precise abnormality leading to the excessive excretion of ALA and PBG in acute porphyria, however, remains to be elucidated.

The time is ripe for a comprehensive review of our knowledge of the porphyrins and of the diseases associated with disturbances of their metabolism and we are fortunate in having this book, the senior author of which has contributed so much to this subject since he first recognized the importance of porphyrins at a time when they were little more than biochemical curiosities. Dr. Goldberg has made important contributions both to the clinical aspects of the disease and to the mechanisms of production of the experimental porphyrias. The first chapter concerns general aspects of the porphyrias, their classification and geographic distribution, and the second discusses the chemistry and biosynthesis of the pigments themselves and their distribution in the body. There follow successive chapters on congenital (erythropioetic) porphyria, acute intermittent porphyria and the various forms of cutaneous porphyria. Each is described from both the clinical and the chemical points of view. Subsequent chapters concern diseases of porphyrin metabolism other than the porphyrias, the incidence of porphyria in animals, and include an account of the various forms of experimental porphyria. It is a pity that the recent discovery of griseofulvin-induced porphyria was made too late to be included.

Nevertheless, it is difficult to praise this monograph too highly; the format and style are well up to the standard set by the series. In particular, the photographs of patients and the microphotographs of tissues, coloured when demonstrating the presence of fluorescent porphyrins, are excellent and the list of references is up to date to 1961. It is unlikely that this book will be read by all clinicians, all pathologists or all biochemists; it will be of very great interest to clinicians who have actually encountered patients with disorders of porphyrin metabolism, especially neurologists who have seen the devastating sequelæ the disease can leave in the nervous system, and dermatologists who will learn of the various forms of porphyria which can cause photosensitivity. To the pathologist the subject illustrates beautifully the way science and medicine have developed to mutual advantage, while for the biochemist the book reveals many remaining problems especially in determining the details of abnormalities in enzymatic syntheses responsible for these interesting diseases.

C. H. Gray

RARE EARTH AND ACTINIDE SPECTRA

Operator Techniques in Atomic Spectroscopy

By Prof. Brian R. Judd. (McGraw-Hill Advanced Physics Monograph Series.) Pp. ix+242. (London and New York: McGraw-Hill Book Company, Inc., 1963.) 77*s*.

IT was round about 1948 that the electron spin resonance group at Oxford began to investigate rare earth salts, and thereby created for themselves an urgent need to

know a good deal more about the spectroscopy of this comparatively unknown group of substances. Fortunately most of the basic theory was already available, in Condon and Shortley's classic book, *The Theory of Atomic Spectra*, and with an extension to take account of crystal field effects, the stage was set for rapid developments in the whole field of the spectroscopy of rare earth ions in solids. In fact, the development did not occur at all rapidly and even excursions into the actinide series did not attract a great deal of attention. Nevertheless a solid core of good work was done, which has served as the foundation for the recent very exciting developments with rare earth solid-state lasers. Much remains to be done, of course, but with many more physicists now engaged in understanding rare earth spectra there is a need to be sure that the theoretical techniques which are used are as powerful as possible.

Now the methods given in Condon and Shortley, and their crystal field extension, have served us well, but there is no doubt that they can be extremely tedious to use. Further, it commonly happens that the end result of a lengthy calculation is quite simple, and one is left wondering whether or not there was a 'better way' of doing it. Well in many cases there was, and it is the purpose of this book to explain what we should have done.

The new method is based on the work of Prof. Racah, who examined in considerable depth the structure of many-electron wave-functions and their associated operators, using, particularly, group theoretical ideas. The result was a very elegant and instructive new way of dealing with problems in atomic spectroscopy, particularly those concerned with unfilled shells of electrons of high orbital angular momenta. Unfortunately the mathematical background is outside the range of knowledge of most spectroscopists, so that having coped with Condon and Shortley they are now faced with an even less familiar field.

Prof. Judd writes extremely clearly and gives his reader every help, with lots of examples and illuminating comments. Even so there is little doubt that a typical response will be to ask whether it is really necessary. The answer will of course depend a great deal on the reader, and the time which he is prepared to devote to what is really a large subject. The average experimental spectroscopist is probably best advised to leave this topic alone, unless he is a particularly good mathematician, though he should certainly look through the book and try to obtain some feeling for the mathematical techniques which his theoretical colleagues are using. The theoretical spectroscopists, on the other hand, should delve much more deeply, for this is the modern way of dealing with many-electron atoms, and here is one of the principal exponents explaining it to them. They should, indeed, read carefully and thank Prof. Judd for leading them so smoothly into this comparatively difficult and unfamiliar branch of theoretical physics.

K. W. H. Stevens

METALLURGY, ARCHÆOLOGY AND THE BRITISH ISLES

Metallurgy in Archaeology

A Prehistory of Metallurgy in the British Isles. By Dr. R. F. Tylecote. Pp. xvi + 368 + 28 plates. (London: Edward Arnold (Publishers) Ltd., 1962.) 84*s*.

"THE original object of this book was to gather together the wealth of information on metallurgical aspects of archaeology contained mainly in the appendices to excavation reports. . . . It was not long before it became clear that the information available amounted to a prehistory of metallurgy in the British Isles," and it is to these Islands that the author's attention is mainly, though by no means exclusively, directed. It will come as somewhat of a surprise to many readers to discover how great this wealth, in fact, is. In garnering in his harvest, Dr. Tylecote has performed a most valuable service: between seven and eight hundred references to pertinent journals, many quite obscure, are provided and the mere physical labour of making this collection and visiting the museums and other sources of his material is beyond praise. In this work he pays generous tribute to the help accorded by his wife. It must not, however, be assumed that this is a mere catalogue; the information brought together has then been sifted and welded into coherency, a task for which the author, both a trained engineer and metallurgist, is unusually well qualified to perform.

Starting with the native metals, and such gold as has been recorded in England, Scotland, Wales and Ireland—a nugget weighing 21·5 oz. was found in Ireland in the eighteenth century—the story is carried on to the final development of the blast furnace and the production of molten iron around 1500 A.D. The earlier chapters, necessarily devoted to the non-ferrous metals, are concerned with copper and its alloys, the production of tin and tin alloys, lead and silver. How much work has in fact been done is demonstrated by the 22 pages of analyses of copper and bronze samples alone.

Meteoric iron of indigenous origin is practically unknown in Great Britain, the Iron Age being introduced by Hallstatt people from the Continent probably between 500 and 400 B.C. It is reasonable to assume, therefore, that these immigrants were already familiar with bellows-driven bowl furnaces, knew something of the strengthening effect of carbon on iron, but were more or less ignorant of the technique of hardening carburized iron by water-quenching. After discussing the iron industry during the Roman occupation the author has a relatively short, but very important, chapter on iron during the 'Dark Ages' and the early medieval period. His conclusion is interesting. "In conclusion, we can say that there has been no advance on the pre-Roman techniques themselves, but that the knowledge of the processes of carburizing and heat-treatment is now more widespread" and "in certain cases brought together with great effect". In the Anglo-Saxon-Viking period "it would appear that smelting and smithing techniques carried on where the pre-Roman technique left off".

In the course of his discussion of pre-Roman iron, the author has collected the available data relating to no less than 71 of the curious 'currency bars'. This information is subjected to a rough statistical analysis, the whole representing perhaps the most detailed discussion of these pieces yet available and amounting to a real and intensely interesting piece of research.

Sandwiched in between the accounts of the non-ferrous materials and iron is the longest chapter in the book on methods of fabrication. This is a section of great value and is outstandingly well done. Those whose curiosity is still unsatisfied will find, in the 151 references, food for still more intensive study. Here, as indeed throughout the book, the sketches add immensely to the descriptions. Details of more than a hundred crucibles found in the Islands, their provenance, date, shape and capacity, are given; analyses of typical slags, and descriptions of methods of manufacture of vessels are but part of the ground covered. Methods used in the manufacture of gold torcs, how the late Bronze Age sword was repaired, the way the Irish trumpet was constructed or the reasons why certain castings of a similar date had had to be scrapped are examples of the range of problem discussed.

It would be too much to expect that at all points Dr. Tylecote's views coincide completely with those of any reviewer, but that this is a thoroughly reliable account of a subject which bristles with difficulties there can be no doubt: the illustrations are excellently reproduced and the index all that the most exacting reader could need. The labour which has gone into its preparation is immense and the result a work of outstanding value and interest.

F. C. Thompson

Biophysics of the Striated Muscle

By Prof. E. Ernst. Pp. 398. (Budapest: Publishing House of the Hungarian Academy of Sciences, 1963. Second edition.) 9.00 dollars.

THIS volume is a new English edition of the author's *Die Muskeltätigkeit* published in 1958 and reviewed in *Nature* (183, 1008; 1959) by Dr. D. R. Wilkie. Prof. Ernst has taken the opportunity to add new material to each chapter, and specialists in the field should welcome the work, particularly for its comprehensive survey of the literature, some of which is not very well known to English-speaking physiologists. There are sections on muscle structure, contraction, volume changes, electrical excitability, metabolism and theories of muscle contraction.

The fullest treatment is given to work which has been done in the author's own laboratory, but he is aware of this bias and, in this connexion, he quotes Empedocles: "Each of us believes only what he has encountered during his random wanderings and nevertheless prides himself on having found the whole". Professor Ernst's wanderings have led him to an outlook which differs considerably from that current in English physiology and one valuable consequence of this is that it has led him to experiments (for example, those on volume changes) which may not otherwise have been performed.

The author is very critical of some present-day theories of excitation and contraction but, although some of the criticisms deserve careful attention, others are based on misunderstandings of the theories. Thus, in discussing excitation (p. 212), he argues that "contrary to expectation impedance drops after the onset of the action current". In fact, the delay in onset of the impedance drop is perfectly well explained, indeed required, by the Hodgkin–Huxley theory. The explanations of the action potential overshoot (p. 210) and the effects of temperature on conduction velocity and spike duration (p. 222) are also misunderstood or ignored and it is not therefore surprising that Prof. Ernst comes to the conclusion that "the excitation of muscle (and nerve) can hardly be explained on the basis of current ion and membrane theory" (p. 223). Although this book will be of value to research workers in muscle biophysics, it cannot be recommended as a general introduction to the subject.

D. Noble

A Textbook of Gynaecology and Obstetrics

By Douglas G. Wilson Clyne. Pp. xxiii+1019+83 plates. (London: Longmans, Green and Co. Ltd., 1963.) 90*s*.

THE preparation of a single volume covering the whole field of obstetrics and gynæcology is an unenviable task, particularly if the author directs his book to teachers. Inevitably some subjects are compressed into small space and there are omissions. For example, in the section on the new-born, important causes of jaundice, such as glucose-6-phosphate dehydrogenase deficiency and galactose intolerance, are not described. Much is also said about vitamin K, but there is no reference to vitamin K_1.

In the chapter comparing hospital and domiciliary confinement the author echoes the Ministry of Health with the statement that almost three-quarters of deliveries take place in "an institution". It is a pity that it is not made clear that at present only just more than half the British mothers can have full hospital facilities as shown by the recent *Perinatal Mortality Survey*, and that many deliveries occur in small units which have the disadvantages of both hospital and domiciliary confinement.

For the most part the material is well chosen and the arrangement of text and references to published work is good. This is a book full of facts and figures which should prove valuable to students.

John Murray

Three Hundred Years of Psychiatry, 1525–1860

A History Presented in Selected English Texts. By Richard Hunter and Ida Macalpine. Pp. xxvi+1107. (London: Oxford University Press, 1963.) 84*s*. net.

THE authors in their preface adopt a refreshingly sceptical attitude towards psychiatry as a science. Psychiatry, they say, "does not possess a body of exact and established knowledge on which all can agree comparable with medicine. Rather it consists of attitudes, concepts, theories and therapies from which each doctor selects what accords best with his predilections, so that one is tempted to say that there is not one body of psychiatry but many psychiatrists". Furthermore, "aetiology remains speculative, pathogenesis largely obscure, classification predominantly symptomatic and hence arbitrary and possibly ephemeral; physical treatments are empirical and subject to fashion, and psychotherapies still only in their infancy and doctrinaire". To escape from present empiricism they turn to history, believing that "the history of a science is the science itself". Their book is built up on extracts from original sources arranged chronologically, and since psychiatry extends well beyond the field of medicine as a physical science they have included "the writings of divines, philosophers, philanthropists, lawyers, men of letters, even self-accounts of patients, as well as Parliamentary Acts and reports documenting society's interests in and care for the insane". The result is a fascinating compendium, richly illustrated by the reproduction of title-pages. It can be recommended as a mine of information to all who are interested in the human mind or in society's reactions to its aberrations.

Brain

Marsilae: Botanical Monograph No. 2

By Prof. K. M. Gupta. Pp. iii+113+40 figures. (New Delhi: Council of Scientific and Industrial Research, 1962.) *Rs*. 16.00, 33*s*., 5.00 dollars.

THIS work is primarily though not exclusively concerned with formal and experimental taxonomic studies on the Indian species of *Marsilea*, and in particular with those four of the nine Indian species recognized by the author which have been available to him as live plants. The bulk of the original material included consists of the results of biometric studies on these four species grown under uniform conditions of cultivation. The main appeal of this volume will therefore be to workers concerned with the taxonomy and biosystematics of this genus. An artificial key to the Indian species of *Marsilea* is provided, and one new species, *M. rajasthanensis*, is described.

The quality of this publication is, to say the least of it, uneven. The photographs of leaflets, pedicel-petiole attachments, and sporocarps, reproduced as Figs. 14, 20 and 21 are poor by any standard, and fail to display adequately the contrasting characters concerned. Diagrams, not photographs, without indication of magnification are selected for the illustrations of chromosomes on Fig. 37. The drawings included on Figs. 29, 30 and 31 do little justice to the figures of Sharp and Delmasy-Feller on which they are acknowledgely based, and the legends provided in the original publications are excluded in their entirety, an omission which is the more deplorable since Fig. 29, purporting to show microsporogenesis in *Marsilea quadrifolia*, does in fact illustrate stages in spermatogenesis, and the illustrations on Fig. 30, described as megasporogenesis in *M. diffusa*, do in fact depict the development of the female gametophyte. Furthermore, certain of the drawings included on Fig. 31, labelled as embryogenesis in *M. diffusa*, only become explicable on reference to the original legends of Delmasy-Feller, when it is discovered that half the illustrations refer not to stages in embryogenesis, but to abnormalities in the development of the female gametophyte!

J. D. Lovis

MAN AND HIS FOOD*

By Sir WILLIAM SLATER, K.B.E., F.R.S.
Formerly Secretary, Agricultural Research Council

THE impact of science on the duration of human life has been widely discussed. It is not intended here to examine this great problem in detail, but to set out only the few facts needed to illustrate the magnitude of the task of feeding the growing millions.

The population of Europe is expanding at 6 per cent in each decade, those of Africa and Asia at 21 and 27 per cent, respectively. All these growth-rates are tending to increase. Since 1950 the world population has increased by more than the total population of Europe including the U.S.S.R., and its yearly growth is greater than the present population of Great Britain.

The only final solution to this problem is a limitation of the rate of reproduction. Unless this is achieved, the population pressure must ultimately result in famine, revolution and war.

It is generally accepted that the world population will have doubled by the end of the century, and that the food required will be twice that now available to provide a diet little or no better than that of to-day. If the diet in the poorer countries is lifted to the level in the wealthier, it is estimated that the increase required would be six-fold.

What are the chances that the lower target can be reached or even exceeded to give everyone a better standard of living? To answer these questions it is necessary to study the limiting factors in food production by orthodox farming and other sources of food which may be available in A.D. 2000.

To grow crops the farmer needs land and water, energy from the Sun, nutrients from the soil or through the foliage and carbon dioxide from the atmosphere. The land suitable for farming is limited. In 1959 there were just over eleven acres of land surface in the world for each person. Of this, about one acre was under arable cultivation or tree crops, two acres under permanent grassland, three and a half acres under forest and four and a half were waste lands. Much of the latter is too mountainous or lies too near the poles for cultivation. What is left is desert, primarily through lack of water, but in some instances due to a deficiency of plant nutrients. With double the population, all these figures will be halved, except in so far as there can be redistribution between the types of land use.

The land under forest can make little or no contribution to farming. Much of it is on mountainous hillsides or on shallow soils unsuited for agriculture. Moreover, the timber it produces is needed for man's use. The farmer must, therefore, draw on the waste lands for any additional acreage. This in practice means bringing the deserts into cultivation, which in turn involves irrigation. These lands are barren because no water is immediately available either from local rainfall or from a major river with its source in the region of higher rainfall. Water may be provided either by bringing it from long distances, by sinking deep wells into water-bearing strata, or, if the desert is near the sea, by desalinization of sea-water. The first method involves great expense, and expert knowledge in the construction of dams, pipelines or canals. The poorer nations cannot meet the expense nor have they the technically qualified staff to carry out the work; the planning and financing of these schemes must, therefore, fall on the wealthier. Moreover, major irrigation works call for co-operation between nations in apportioning the available supplies. Deep wells and the essential pumping equipment are also expensive and their siting calls for skilled advice. The desalinization of sea water is at a relatively early stage in its development; the fresh water produced is too expensive for use in field irrigation on any major scale.

If we can assume that the economic and political obstacles can be overcome, the limitation on the extension of cultivatable land by irrigation will depend on the water available in each region. Unfortunately, no precise estimates have been made for many of the most important regions.

While farming can be expected to gain from the lands which are at present waste, it will also lose land to urban development as the population grows.

Any estimate of the increase in land available for food production at the end of the century must, with so many uncertain factors, be highly speculative. It is anticipated, however, that the increase cannot be more than half the area now under arable cultivation and tree crops, which would provide no more than an additional quarter of an acre per head of population in A.D. 2000. Then the farmers of the world will be faced with producing on three-quarters of an acre of cultivated land and one acre of permanent grassland the food for one person which they now produce on one acre of cultivated land and two acres of permanent grassland.

This represents increases of 33 per cent on the cultivated acreage and 100 per cent on the permanent grassland. The additional production on the cultivated land can easily be achieved and should be exceeded. Given an adequate water supply, the chief limiting factor in crop production is the supply of the major nutrients, nitrogen, phosphorus and potash. Surveys made by the Food and Agriculture Organization have shown that there is a high correlation between crop yields and the fertilizers used. The highest returns from the use of more fertilizers will be in those areas where the present applications are lowest. Thus, in Britain, while many farmers are probably applying the optimum amounts of fertilizers which the existing crop varieties can use, others could increase their yields by higher dressings. It would not be asking too much to expect, in Britain, an overall increase in crop yields of 20 per cent if all farmers made full use of fertilizers.

The return from higher fertilizer applications will vary from country to country, but in few will it be less than that in Britain. In large areas of the world where there is most need for food, the amount of fertilizer used is the smallest; as a result, the yields are the lowest and the response to higher applications will be the greatest. On the other hand, in some large grain-growing areas such as the Canadian prairies, the rainfall is the factor limiting, yields. Here, without enormous expense on irrigation fertilizers would have little effect.

Taking the world as a whole, it would not be unduly optimistic to expect that higher fertilizer usage could increase the output of existing crop varieties by 50 per cent. If the plant breeders can produce new varieties, capable of making better use of the fertilizers available, or of absorbing still higher dressings, then this figure might well be exceeded.

In countries such as India where every scrap of vegetable material is eaten by man or animals and the animal dung is dried and used as fuel, the soil has become denuded of organic matter, and as a result has lost its capacity to

* Substance of the Sanderson-Wells lecture delivered at Senate House, University of London, on May 21.

hold water or plant nutrients. If yields are to be obtained commensurate with the fertilizer used, steps must be taken to replace this lost organic matter. This will involve outside help in making available alternative fuel supplies or supplementary food to enable the farmers to grow green crops either to plough in or to feed to stock the dung of which can be returned to the land.

It is well established that once farmers begin to use more fertilizers and obtain heavier crops, they take steps to protect them against pests and diseases. Thus, the first increases in the amount of fertilizer used, where the applications have previously been low, evoke a greater response than could be anticipated from experimental evidence.

How much this awareness of the need to protect crops and the willingness and ability to do so will contribute to increased yields is again a matter of guesswork. To obtain a major contribution to the world's food supplies by crop protection it will be necessary to overcome ignorance, prejudice and superstition. Some gain, however, must result, and this can be taken into account in any final estimate.

The problem of assessing the potential production from the permanent grasslands is even more difficult than that of the cultivated land. The term 'permanent grassland' covers every type from the famous fattening pastures of Leicestershire to the virtually barren lands of India which carry a poor grass sward for a short time after the rains, or, again, from the lush valleys of the Alps to the sparse vegetation on the hills of the Middle East. Much of the permanent grassland is already giving the maximum yield of fodder that can be expected. The outstandingly good pastures can scarcely be improved, and many of the worst will not repay treatment. Between these extremes there is a wide range which can be improved by irrigation, the use of fertilizers and re-seeding with superior strains of grasses and legumes.

Grasslands produce human food only through the ruminant. The proper management of the sward, so that the animals grazing it get the maximum amount of keep from a given area and the ability of the stock to yield the greatest quantity of human food from the food they themselves eat are equally as important as the productivity of the sward.

By improving every stage in the production of human food from permanent grasslands, there is little doubt that the output from some part of the area could be doubled; in specially favoured places this increase might well be exceeded. What is not known is how the total permanent grassland is spaced out along the broad spectrum from the one extreme where there is no possibility of increasing the yield, to the other where twice the yield or even more can be obtained. On this depends the average increase throughout the world. The chance that the overall yield of the world's permanent grasslands can be doubled by A.D. 2000 is, however, remote.

Much of the human food obtained from grassland is the high-quality animal protein which is so seriously lacking in the diets of many people. A failure to double the output will mean less milk and meat per head of population. This danger may be, to some degree, avoided if part of the world's grasslands were brought under the plough, to form part of an arable rotation. The three-quarters of an acre of cultivated land per head of population, which could be available by A.D. 2000, would yield, with proper management, enough arable crops to meet human needs, so that the produce of any additional land won from permanent grass could be fed to non-ruminant pigs and poultry or used to supplement the grazing intake of cattle. Except where the most productive grassland was taken, there would be some gain in overall productivity.

Taking all these factors into account, it is difficult to believe that, however great the effort to produce more from the land, the food available from this source for each human mouth in A.D. 2000 will be as much as to-day. In so far as the effort falls short of the maximum, the gap will be widened.

We must, therefore, look for other means of increasing food supplies. One of the most promising of these is the elimination of waste between the farms and the urban centres of population. In the better developed countries this wastage is being eliminated by the prevention of damage by animal and insect pests and the control of spoilage by micro-organisms. More food is being processed on the farm and in the factory, where the non-edible portions can be fed to stock or returned to the land. In the less-developed countries there is a high percentage of waste in store; for some crops in tropical countries this is placed as high as 30 per cent. An attack on this loss of human food could do much to help to close the gap left by the inability of the farm lands to meet the world's growing needs.

Another source of additional food can be sought in the sea and inland waters; the increased supply of fish would do much to meet the shortage of high-quality protein. We are already in trouble with our fishing on the shallow continental shelves of the northern hemisphere. There is, however, a possibility of developing fishing in the deeper waters of the oceans and in some areas of the southern hemisphere. We know all too little of these possibilities and no time should be lost in examining them. We can underestimate them and so overlook a valuable source of food or we can exploit them unwisely and so destroy an important potential food supply.

The cultivation of fish in ponds also holds out hope of more high quality food. Fish culture will, however, occupy land and require a supply of water and so compete with agriculture except where it can be combined with crop production as in the paddy fields.

Another source of protein is the direct extraction of this material from green crops, which would otherwise have to be converted by ruminants with considerable loss before it was available as human food. Processes for the preparation of edible material from this source are being developed and show promise for the future.

Finally, another unusual form of food production is in the experimental stage. It consists of the growing of micro-organisms on by-products of the petroleum industry and inorganic nitrogen. It is too early yet to estimate the significance of this new venture, but it may in the future prove to be of great importance.

One factor, which is common to all aspects of the problem of feeding the doubled population at the end of the century, is the lack of definite knowledge of the facilities available. More information is needed about the world's land surface, and in particular about the nature and distribution of areas capable of development for cropping. We must know more about the land classified as permanent grassland. At the same time, we need to study all sources of water supply and relate them to the areas where they can be economically used. Much more research is needed on the potential fish supplies in the deeper oceans and on the methods suitable for their economic exploitation. Finally, we must work on and assess the possibilities of unorthodox methods of food production.

Can all our efforts in food production meet the world's needs in A.D. 2000? No one can answer this question with absolute certainty, but most of those who have investigated the problem believe that they could and that some contribution could be made to the relief of hunger and malnutrition. But to achieve this, there will have to be an awareness of the problem throughout the world, a willingness to give up superstitions and prejudices often deeply ingrained and sincerely held, a determination by all nations to put this problem first on their list of priorities and a degree of co-operation among the nations which has so far not emerged.

OCEANOGRAPHY AT THE SMITHSONIAN INSTITUTION

By Dr. I. E. WALLEN
Assistant Director for Oceanography, Museum of Natural History, Smithsonian Institution, Washington

THE Smithsonian Institution, chartered for the "increase and diffusion of knowledge among men", has traditionally been deeply involved in research on marine organisms. However, since the Institution operates no ships, its potential contribution to the National Oceanographic Program was not fully realized in the initial phases of the development of that Program. It soon became evident that, of all federal agencies, the Smithsonian Institution has the outstanding collections of marine specimens, as well as exceptional staff capabilities in the area of marine systematic biology. Therefore, the Interagency Committee on Oceanography was prompt to recommend that the Institution consider expanding its basic staff and facilities in this area and thus increase its contribution to the national oceanographic effort.

As a result of the increased international and national effort in oceanography. many biological and geological collections are expected to be brought to the Smithsonian Institution. During the International Indian Ocean Expedition, which is now proceeding, at least 44 ships from 27 nations will collect specimens in the area of the Indian Ocean. The two phases of the International Co-operative Investigations of the Tropical Atlantic will include 30 oceanographic cruises, involving 16 vessels from at least 10 nations. Twenty-two U.S. Coast Guard vessels occupy ocean stations in the Atlantic and Pacific Oceans and many make marine collections. Nine oceanographic institutions along the coasts of the United States utilize more than 21 ships to collect oceanic information. Ships of the Coast and Geodetic Survey, the Naval Oceanographic Office, the Bureau of Commercial Fisheries, and other federal agencies gather oceanographic materials and data as a part of their missions.

Many of the ships taking part in the foregoing cruises make net, dredge, trawl, and coring collections of natural history materials, especially plankton and sediments, to study the productivity of the sea, to examine the organisms in relation to the physical and chemical environment, to study the evolution of the Earth, and for other purposes. Although much remains to be developed in the way of sampling techniques and interpretation of marine populations, it is relatively easy to collect specimens. On the other hand, it is extremely time-consuming to identify and count the members of the populations.

Background of Smithsonian Institution Oceanography

Before the founding of the Smithsonian Institution in 1846, at least seven principal exploring expeditions had been conducted by the U.S. Government, including the first oceanographic expedition. During 1838–42, Captain Charles Wilkes led a round-the-world expedition to investigate the commercial whaling industry in the Pacific. His staff included naturalists, geologists, botanists, mineralogists, taxidermists and a philologist. The extensive collections which resulted were transferred to the Smithsonian Institution in 1857.

In his book *Sons of Science* (Henry Schuman, 1949), Paul H. Oehser gives the following account of the Smithsonian's early involvement in expeditions, as reported by the then assistant secretary Spencer F. Baird:

"In his 1954 Report, Baird described twenty-six important explorations undertaken during the preceding two years, including six Pacific Railroad surveys. Of the Smithsonian's part of these he wrote:

" 'With scarcely an exception, every expedition of any magnitude has received more or less aid from the Smithsonian Institution. This has consisted in the supplying of instructions for making observations and collections in meteorology and natural history, and of information as to particular desiderata; in the preparation, in part, of the meteorological, magnetical, and natural history outfit, including the selection and purchase of the necessary apparatus and instruments; in the nomination and training of persons to fill important positions in the scientific corps; and in the reception of the collections made and their reference to individuals competent to report upon them; and in employing skilful and trained artists to make accurate delineations of the new and unfigured species. Much of the apparatus supplied to the different parties was invented or adapted by the Institution for this special purpose, and used for the first time, with results surpassing the most sanguine expectations'."

During his years as assistant secretary of the Smithsonian Institution, Dr. Baird spent several summers on the Atlantic coast collecting fishes. As a result of his efforts the United States Fish Commission was established by Congressional action in 1871 with headquarters at Woods Hole, Massachusetts. The initial voyages of the *Albatross*, *Fish Hawk* and other vessels were oceanic exploratory cruises in search of commercial fishery populations. The work on the systematics of fishes, as well as continued studies on other marine vertebrates, invertebrates and algae, was left within the Smithsonian Institution, although the responsibility for commercial fishes and for fishing explorations which might lead to commercial development was transferred to the Fish Commission in the Department of Commerce in 1903, and later to the Department of Interior.

Within the Smithsonian Institution, the principal effort in oceanography is concentrated in its largest bureau, the U.S. National Museum, which is further divided into a Museum of History and Technology and a Museum of Natural History. In the latter administrative unit the position of assistant director for oceanography has recently been established. The designated responsibilities of this assistant director include: (1) aiding Museum staff members in their marine research; (2) planning, developing and operating for the Institution a Sorting Center for marine biological and geological materials; (3) maintaining liaison with ocean-going vessels and scientists to collect biological materials; (4) helping to recruit outstanding marine sediment and taxonomic scientists; (5) bringing the Smithsonian oceanographic programme to the attention of scientists; (6) representing the Smithsonian Institution on various committees and councils concerned with oceanography.

Staff members of the Museum of Natural History who are involved in the oceanographic programme are located in the Departments of Zoology, Botany and Geology. As described here, the Smithsonian Oceanographic Sorting Center is a new separate unit, reporting directly to the assistant director for oceanography.

Oceanographic Research

Since it was obvious that the number of marine scientists on the existing staff was insufficient to meet the predicted need for the oceanographic programme, additional specialists are being employed to permit critical study of marine

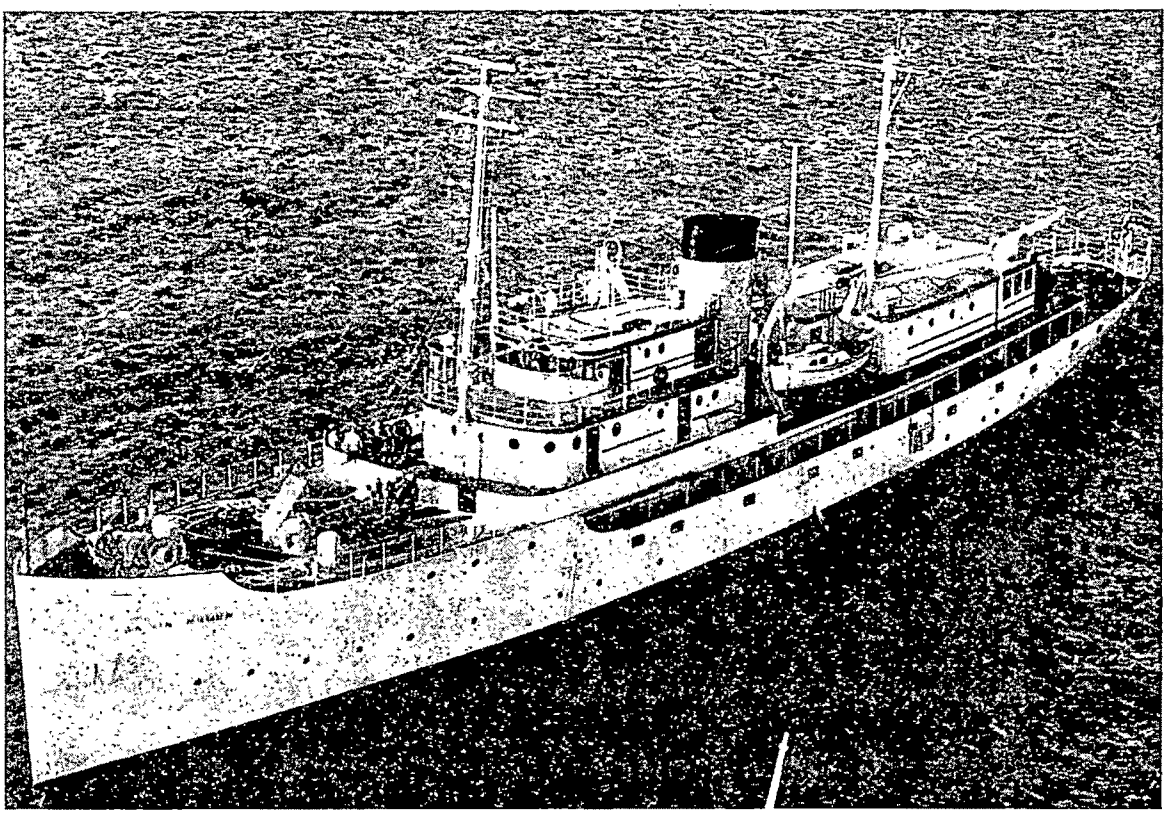

Fig. 1. National Science Foundation vessel *Anton Bruun*

collections that come to the Smithsonian Institution. The present policy of providing space and facilities for outside specialists and graduate students to work in the Museum of Natural History is being continued, and reciprocal arrangements for Museum personnel to work in other laboratories are encouraged.

Recognizing that a scientist often may do much valuable research on personally collected materials, the programme of the Smithsonian Institution provides for staff participation in marine expeditions. Eleven marine scientists from the Smithsonian Institution will participate in the International Indian Ocean Expedition and three are participating in the Tropical Atlantic Expedition.

In order to give staff scientists more time for research and exploratory field work, the Institution hopes to provide for an increase in the number of technical assistants, in supporting services, and in funds for travel. In addition to participating in research cruises, staff scientists are expected frequently to examine reference materials in other museums, thus achieving greater completeness of coverage and accuracy of data.

Adequate study of some materials collected by the oceanographic programme will require study of related materials from freshwater and land; thus it is anticipated that all divisions will continue to process fresh-water and terrestrial specimens, in addition to the handling of marine organisms.

The internal organization of the Museum of Natural History permits oceanographic work to be conducted in several divisions within three departments. Studies of recent invertebrates are at present carried on in two divisions of the Department of Zoology—the Divisions of Marine Invertebrates and of Molluscs. Staff members of these divisions have collected in the Atlantic, Pacific and Indian Ocean areas during the past year. Because of the complexity of the taxonomic groups under consideration, additional administrative units in the area of marine invertebrates may prove desirable.

In reference to marine vertebrates, personnel from the Divisions of Fishes, Reptiles and Amphibians, Birds, and Mammals (all within the Department of Zoology) contribute to the oceanography programme. Vertebrate specialists from the National Museum have actively participated in the International Whaling Commission and on Navy shark panels for many years.

One of the areas particularly in need of strengthening at the Smithsonian, as in other organizations, is that dealing with marine plants. At present, one staff member of the Division of Cryptogams (in the Department of Botany) is participating in the International Indian Ocean Expedition, conducting a study of nannoplankton dinoflagellates with the *Anton Bruun* (Fig. 1) as his base.

Within the Department of Geology, the present Division of Invertebrate Paleontology and Paleobotany curates collections of minute fossil and recent organisms including Foraminifera, Radiolaria and coccoliths, which, in association with bottom sediments, have important implications for oceanography. The prodigious numbers of specimens that will be collected during the oceanographic cruises should provide unprecedented opportunities to obtain information on the paleoclimatology of marine environments as well as on the evolution and biogeography of both fossil and recent organisms.

The Smithsonian Institution is the principal repository of geological collections made with the use of Federal funds; similarly it serves as a repository for cores, dredged-sediment samples, and rocks from the ocean bottom. In anticipation of a large increase in the receipt of oceanic sediments, research and curating are planned in such fields as petrology, sedimentary petrology, clay mineralogy, carbonate sedimentology, and geochemistry.

Manpower recruitment. The National Academy of Sciences Committee on Oceanography noted in its 1959 report (Brown, Harrison *et al.*, *Oceanography* 1960–1970) that "many lines of marine research depend upon precise definition of species". It recommended that museums

"be given financial support so that this kind of work can be carried forward". The shortage of systematists was recognized and a modest appropriation was suggested to keep this field of biology from "dying out".

Recently the Interagency Committee on Oceanography of the Federal Council for Science and Technology asked its manpower and training panel to investigate the manpower requirements for oceanography. The preliminary report of this Panel concluded that in view of the tremendous quantities of marine specimens being collected by oceanic survey and research cruises, an inadequate number of taxonomic scientists is available to process the collections promptly and adequately. Since taxonomy is basic to effective research in most biological fields, the shortage of taxonomists has very serious implications for the marine sciences, particularly during the present exploratory phases.

Although hoping to recruit new staff scientists, the Smithsonian Institution recognizes that specialists are not available for employment in each of the more than 60 major groups of marine specimens which will be collected. Co-operative arrangements and contracts with other public and private organizations will continue to encourage the use of specialists wherever they are located in the United States and abroad.

Smithsonian Oceanographic Sorting Center

One of the principal delays in the processing of marine materials has been the separation of bulk collections into units that can be handled effectively by specialists. Such collections include heterogeneous groups of plants and animals, often mixed with sediments. Many hours must be spent in carefully picking over the collections to separate them into the major components for identification and population counts. For example, the sorting of one pint of tropical marine plankton into biological groups may take the full time of one person for as much as twenty days.

In order to increase the efficiency of processing of samples and thus to permit more rapid publication of data, the Smithsonian Institution has established in Washington, D. C., the Smithsonian Oceanographic Sorting Center. The Center has employed personnel to follow the progress of marine biological samples from collection to publication and to assist oceanographers through all phases of the handling of specimens.

Although the Sorting Center is temporarily located in leased space, plans are being developed to move it to another localty in Washington where it will be adjacent to some of the oceanic activities of other agencies. It is anticipated that competence will be available in the Center to handle all types of collections of marine fauna, flora and sediments.

Separation of collections.—The initial separation into major groups will be performed by a staff of technicians under the supervision of experienced personnel who are aware of the various difficulties that may be encountered. It is hoped that many of the marine scientists who make collections will visit the Sorting Center to assist the supervisors in the training of technicians in the proper separation of the organisms within their interest.

Identification of specimens. It is expected that arrangements will be made as necessary on either a research or a service basis for the identification by specialists on each group of specimens which is sent to the Sorting Center. Lists of specialists on the various marine taxa will be obtained and maintained in the sorting centre. The opinion of advisory committees will be used to assure that specimens are sent to the best qualified and willing specialists. Specimens will be made available for research by qualified scientists without regard to institutional affiliation.

When collected materials are of interest primarily for distributional studies, it is anticipated that service identifications will be required. In such cases, when publication is not anticipated by the persons making the taxonomic determination, the Sorting Center hopes to defray expenses of such identification.

Provision of data. The Sorting Center will provide data concerning the composition of collections, including algae and sediments, by field station. It should be possible to relate such information to physical and chemical data from the same station on file in the National Oceanographic Data Center for ecological and other studies.

Progress reports on the processing of biological data from major expeditions will be provided to scientists on request. This service will assist biologists in co-ordinating their studies with the multi-agency or multi-national programme under which the data were collected. To avoid the overloading of individual scientists and to expedite the processing of collections, a current list of identification work in progress by various scientists also will be maintained.

In so far as is feasible, a programme for the recording and retrieval of data will be undertaken with the co-operation of National Oceanographic Data Center, Science Information Exchange, the U.S. Bureau of Commercial Fisheries, and other groups, as well as the Food and Agriculture Organization of the United Nations and other international groups. As appropriate, the Center will investigate the presentation of marine biological data through biogeographic maps and other devices that illustrate distribution and abundance of marine organisms.

Since the Sorting Center exists as a service organization, rather than as one dedicated to research, it is expected that encouragement will be given to the preparation and publication of processed data outside the Center. Normally, only when an obvious need exists for more rapid data processing, or when the data might not be available otherwise, would the staff of the Sorting Center publish the data on its own volition.

Co-ordination function for expeditions. While the Sorting Center, as outlined here, should meet the most direct needs for specimen processing, it is hoped that several inadequacies in the present mechanism for treatment of marine biological materials can be remedied. It is planned that the Center staff, as requested, assist with all aspects of the processing of marine collections taken during multi-agency and multi-national expeditions, such as the International Indian Ocean Expedition.

During the planning of expeditions, the Center will serve as a source of information on such items as methods of preservation and the storage, labelling and shipping of collections. The Center will maintain lists of biologists desiring to participate in marine expeditions to specific areas and the staff will provide information to them on the availability of research space and on alternative cruise plans.

Through the preparation of summaries of existing data the needs for biological information from areas of the world's oceans will be brought to the attention of scientists. For example, the Smithsonian Institution has prepared and distributed an illustrated field guide to marine and insular birds of the Indian Ocean for the use of participants in the International Indian Ocean Expedition. The guide summarizes published information on the biology of birds and suggests the sorts of additional fundamental observations which are needed. A guide to the scombroid fishes of the Indian Ocean has also been prepared, and additional aids for field identification and data gathering will be distributed as they are available.

Availability of space for research and training. It is not expected that the Sorting Center in Washington, D.C., will process all biological collections, for some scientists will continue to feel that the only satisfactory sorting of special collections is that performed under their immediate supervision. In such cases, the Sorting Center can provide two kinds of services. Individual scientists, having limited

space at their own institutions, may use the facilities of the Center and request the assistance of the staff in separating marine materials of special interest. Preservatives, containers and other necessary support can be made available on reasonable notice and after appropriate arrangements.

A second function of the Sorting Center could be the training of technicians for sorting, packaging, shipping, preserving and other scientific handling of specimens. Under appropriate sponsorship persons desiring to work in the Sorting Center may participate, under supervision, in all phases of the operation.

Distribution of Specimens

Although last in this discussion, it is obviously of first importance to scientists that specimens be made available in a number of places for future study. The Sorting Center will use advisory committees of Government and non-Government scientists to plan the equitable distribution of the specimens to appropriate well-curated museums for permanent storage. On the advice of such committees it is anticipated that the U.S. National Museum and other museums, on expression of their willingness to accept specimens, will receive materials for their collections. The specimens not otherwise claimed or distributed will be placed in the U.S. National Museum, to be available for study under the usual procedures.

In summary, the Smithsonian Oceanographic Sorting Center is visualized as a service organization for the benefit of scientists and scientific organizations both within and without the Federal Government. Collections submitted for processing will not automatically become the property of the U.S. National Museum. Indeed, it is the desire and the intention of the Smithsonian Institution to aid the interested scientific community to make an equitable distribution of all such materials, placing them in institutions throughout the country where they will most effectively advance the biological and geological aspects of the national oceanographic efforts.

DIRECTORATE OF OVERSEAS SURVEYS

BRIGADIER MARTIN HOTINE, director since 1946 and adviser on surveys successively to the Secretary of State for the Colonies and to the Secretary for Technical Co-operation, will retire on October 10 after forty-six years service to the Crown, and after making a very substantial contribution both to the scientific and technical basis of surveying and to its practical application. Brigadier Hotine was commissioned in the Royal Engineers in 1917; after service in Persia, Iraq and India he was appointed research officer to the Air Survey Committee during 1925–28, and was responsible for the development of the Arundel method of triangulation from air photographs. This, and other practical methods of air survey not involving the use of the more elaborate plotting instruments developed on the Continent, were described in his book, *Surveying from Air Photographs*, which was published in 1931; and many techniques still in use are based on them. In many respects this is still the basic text-book on the subject.

After a period of service at the War Office he spent two years in Central Africa on observations for the 30th arc of meridian, during which he made important contributions to the procedures for observing geodetic triangulation and to the precise measurement of first order bases with invar tapes, where accuracies better than one part in a million were required over distances of several miles. In particular, his paper on "The General Theory of Tape Suspension on Base Measurement", published in the *Empire Survey Review*, started from fundamental principles and led to important changes in the handling and in the techniques of measurement using invar tapes, which were at that time the only way of achieving these accuracies over such distances.

Another important result of his experience in Africa was his realization of the survey requirements of underdeveloped countries and of the need for a central agency to carry out the major tasks of geodetic control, aerial photography and basic topographical mapping, which later bore fruit in the Directorate of Overseas Surveys. On being posted to the Ordnance Survey in 1933 he was immediately concerned with an appraisal of the state of the control framework of Great Britain, which had been established in the nineteenth century; and his work led to the decision to re-triangulate the country. The work began in 1935 under Hotine's energetic direction, and the methods and procedures he then devised were generally followed until the end of the triangulation in 1962.

With the outbreak of the Second World War, he was posted to General Headquarters, British Expeditionary Force, and his technical instructions did much to inform junior survey officers about the French triangulation system. After Dunkirk he served in East Africa and Greece, returning to the War Office to become, for the rest of the War, the director of Military Survey and chief of the Geographical Section, General Staff, in 1941. There he was responsible through the Military Survey Service for meeting the needs of the defence services for maps, aeronautical charts and survey data for all their military operations throughout the world. In particular, he created a close working arrangement with the mapping services of the United States. He left the Army in 1946 so that his services could be made available to set up and direct the organization which has now grown into the Directorate of Overseas Surveys. The Directorate started with an establishment of about 180 in temporary accommodation at Bushy Park, and was transferred to its present offices at Tolworth in 1951, where its staff amounts to about 450. During the seventeen years of its existence, the Directorate has produced original topographical mapping, mostly at 1/50,000 scale, of well over one million square miles, most of it in Commonwealth countries (both dependent and independent) in Africa. The Directorate continues to give its services to overseas countries as part of the contribution made by Her Majesty's Government through the Department of Technical Co-operation to development overseas, and it is at present operating in more than thirty overseas countries.

This kind of wholesale survey and mapping of underdeveloped countries posed a number of fundamental questions to which Brigadier Hotine and his staff had to find answers. The smaller scales originally envisaged were found to be inadequate for development planning, and the scale of 1/50,000 was generally found to be the most suitable. From the start very high standards were set in the accuracy and in the beaconing of the triangulation framework so that this would be permanent and adequate for the future amplification of control for larger scale mapping of particular projects or areas. In the same way, the maps issued by the Directorate were designed on regular sheet lines and to a specification rigorous enough for their forming part of the national map system of the country concerned, though the actual areas were covered in the order of priority dictated by its development plans.

These higher standards meant a slower output, but they had the advantage that the maps and survey framework were of permanent value, and available for many uses, instead of being restricted in value to a specific

project. There were, however, cases where the urgent requirements of particular projects prompted the production of maps on little or even no control, showing detail only, without contours. This saved time which would have been spent on the extra ground work required for plotting the contours, and it was possible to add the contours in subsequent editions when control had been fixed.

At the beginning and until 1950 the Directorate relied entirely on photographs taken by the Royal Air Force; but in later years considerably more use has been made of air photographs taken on contract by civilian firms. When precise distance measurement on the ground by radio became a practical proposition with the development of the tellurometer in 1956, the Directorate was the first extensive user of this equipment and was able to increase its rate of establishing control frameworks by two or three times and to carry out some tasks hitherto regarded as impracticable. Before the establishment of the Department of Technical Co-operation there was frequently a risk that work of technical assistance started in the Colonies under arrangements for colonial development and welfare would be interrupted when these countries achieved independence. The Directorate of Overseas Surveys had a part to play in averting this, and Hotine's personal visits to overseas countries have played a great part in preserving continuity in survey work.

The use of satellites and the possibilities of space travel have made it specially necessary to consider geodesy as a truly three-dimensional subject instead of regarding it as principally two-dimensional with corrections and modifications to allow for the third dimension, as had been the fashion previously. Hotine has been one of the pioneers in this field and has taken a leading part in the discussions held by geodesists and mathematicians at Venice in 1959, Cortina in May 1962, and Munich in October 1962; indeed, his papers on 'non-classical' geodesy are well known for the lead they have given on this subject.

Brigadier Hotine was president of the Commonwealth Survey Officers' conference in 1955 and in 1959 and again this year. This conference, which is sponsored by the Department of Technical Co-operation, is organized by the Directorate of Overseas Surveys under the direction of the heads of the four Government Survey departments. It succeeded the original conferences of Empire Survey Officers held in 1928, 1931 and 1935 at which the idea of a central survey organization was first suggested. The conference now comprises 200–300 members and has achieved a high standard of discussion, consultation and record due to its careful planning, informal and friendly nature, and to his firm but tactful presidency.

Brigadier Hotine was awarded the C.B.E. in 1945, the C.M.G. in 1949, the Founder's Medal of the Royal Geographical Society in 1947, and the President's Medal of the Photogrammetric Society in 1955. He is an Officer of the Legon of Merit (U.S.A.).

Brigadier Hotine will be succeeded as director and adviser by Mr. G. J. Humphries. From the University of Reading, Mr. Humphries went to Nigeria in 1928 as a surveyor and served in the Army from 1939 until 1946, ending with the rank of lieutenant-colonel. From 1944 he was on Brigadier Hotine's staff at the War Office and was responsible for a large part of the planning and setting up of the Directorate of Colonial Surveys. He was in charge of the organization and running of the field parties as well as acting as deputy to the present director. He was awarded the O.B.E. in 1954.

GAMMA-GLOBULIN VARIABILITY: A GENETIC HYPOTHESIS

By Dr. O. SMITHIES
Department of Medical Genetics, University of Wisconsin

THE large number of antibodies an individual can form is difficult to reconcile with the presumed constancy, at least in the germ line, of the genes controlling γ-globulin structure. A hypothesis is described in this article suggesting a mechanism whereby a few specialized genes could control the synthesis of a large number of different proteins. The hypothesis is consistent with established genetic principles and with present concepts of protein synthesis.

Nature of γ-globulin variability. The three main classes of human γ-globulin, $7S\gamma$-, γ_{1A}, (or β_{2A}-), and γ_{1M}- (or β_{2M}-) globulins, appear to have in common a polypeptide chain with specific antigenic properties determined by the autosomal locus *Inv*[1–4]. The $7S\gamma$-globulins have in addition a second characteristic polypeptide chain with specific antigenic properties determined by the locus *Gm*[5,6]. The γ_{1A}- and γ_{1M}-globulins also have specific antigenic determinants not shared by the other classes, suggesting that two additional genetic loci control the synthesis of a second polypeptide chain in these γ-globulins[4], although no polymorphisms corresponding to these presumed loci have yet been described.

Variations in the electrophoretic behaviour of the polypeptides of different human serum myeloma globulins have been demonstrated by Poulik and Edelman[7] using urea and thiol dissociated proteins. The conditions of the electrophoresis (in starch gels containing 8 M urea) make it very probable that these variations reflected differences in the amino-acid sequences of the constituent polypeptides of the several myeloma globulins. Similar variations have also been observed[8] in the properties of the low-molecular-weight polypeptides of guinea pig antibodies directed against specific haptens, so that variation in the amino-acid sequences of γ-globulin polypeptides seems to be a normal phenomenon. In order to determine the nature and extent of this variability it would be desirable to isolate and study the structure of polypeptides from mono-clonal antibodies. This has not yet been done. However, recent work on the nature of Bence Jones proteins[9] and on the occurrence of proteins with similar properties in the urine of normal individuals[10,11] suggests that Bence Jones proteins provide equivalent material by an 'accident of nature'. Comparisons of the structures of different Bence Jones proteins, which are known to be highly variable, should therefore reveal the extent and types of variation which must be explained by any hypothesis concerning the variability of γ-globulins.

Bence Jones proteins may differ in molecular weight, electrophoretic mobility, iso-electric point, amino-acid composition, *N*-terminal amino-acid, and antigenic character[12]. They can all, however, be classified immunologically[13] as type *A* or *B* (equivalent to types II and I of myeloma globulins[14,15]), and Putnam and Miyake[16] have shown that this classification is correlated with their *N*-terminal amino-acids. All type *B* Bence Jones proteins have the same *N*-terminal amino-acid (aspartic acid or its amide), but the *N*-terminal amino-acids of the type *A* Bence Jones proteins are variable. For example, some type *A* proteins had no *N*-terminal amino-acid residue detectable, while *N*-terminal threonine, leucine, tyrosine

or valine was found in others. Many Bence Jones proteins have been tested for their reactions in the *Gm*- and *Inv*-detecting systems[17,18]. All failed to react in the *Gm*-system, and some also failed to react in the *Inv*-system, but many were *Inv* (a+b−) or *Inv* (a− b+). No unequivocal examples of *Inv* (a+ b+) reactions were found. Usually, but not invariably, type *B* Bence Jones proteins proved to be either *Inv* (a+) or *Inv* (b+); all type *A* were *Inv* (a− b−). Tryptic peptide 'finger prints' have been described by Putnam[19,20] for three type *B* and five type *A* Bence Jones proteins. No two were identical, but those of type *B* shared some 8 peptides out of a total of about 20, and the type *A* Bence Jones proteins also shared some 7–9 peptides. However, Putnam reported that probably no peptides were identical in the tryptic digests of the two types. One of the peptides common to all three type *B* proteins lacked a basic amino-acid suggesting that they share a common *C*-terminal amino-acid sequence, in addition to having aspartic acid in the *N*-terminal position.

Any hypothesis concerning the variability in expression of the γ-globulin loci must therefore be able to explain the presence of different amino-acid sequences in polypeptide chains having identical *N*-terminal amino-acids and some common amino-acid sequences (including the *C*-terminal sequence), which also have enough structure in common to establish an antigenic character (*B*) and the ability to react with the *Inv*-detecting systems. The hypothesis must also account for the existence of an antigenically distinct type (*A*) of polypeptides which have variable structures (including their *N*-terminal residues) and some common amino-acid sequences, but which fail to react with the *Inv*-detecting systems and have overall amino-acid sequences sufficiently different from type *B* to lead to an essentially completely different set of tryptic peptides.

Antibody specificity. Before considering possible mechanisms for producing variable polypeptides from a given set of structural genes, the question must be asked whether variations in the amino-acid sequences of γ-globulin polypeptides could account for antibody specificity. In several cases (for example, ribonuclease[21], alkaline phosphatase[22], human haptoglobins[23]) the secondary and higher orders of structure have been shown to be completely determined by the primary amino-acid sequence of the corresponding polypeptides, as judged by the recovery, without the addition of complex organizing factors, of the native configuration of the proteins after unfolding with urea and thiols. A change in the amino-acid sequence of a γ-globulin polypeptide could therefore give rise to different antibodies directly as a consequence of the changed sequence and/or indirectly by causing a change in the folding of the molecule. However, as pointed out by Edelman and Benacerraf[2], the number of different polypeptides necessary to account for the diversity of antibodies would, on this simple hypothesis, have to be very large. On the other hand, as indicated here, most antibodies probably contain two types of polypeptide chains, both of which appear able to vary[7]. The required variation in primary structure would consequently be much reduced (cf. Edelman and Benacerraf[2]) if the final configuration of the molecule is not fully determined prior to the juxtaposition of both chains, for, in these circumstances, a change in the amino-acid sequence of either polypeptide chain could affect the final configuration of the combining site (even if this site directly involves only one of the chains). For example, if two different γ-globulin polypeptides could have p and q different sequences, then a total of pq different configurations of antibody molecules might be obtained by their mutually determined folding. This suggestion implies that the three dimensional structure of γ-globulin is sensitive to changes in the primary amino-acid sequences of both its constituent polypeptides. Suitable reconstitution experiments with separated polypeptides from different mono-clonal antibody preparations could be used to test this.

The complete determination of antibody configuration by the primary amino-acid sequences of the corresponding polypeptides is probably a necessity in cells which can form antibody in the absence of antigen. However, it is conceivable that the 19*S* antibodies, which are produced only in the presence of antigen by cells with no 'immunological memory'[24], may have configurations in part determined by the antigen. Even if this proves to be the case, the problem still remains of the mechanism whereby polypeptides with many different amino-acid sequences can be synthesized under the direction of a limited number of loci by cells which can multiply extensively and still continue to produce these polypeptides.

Possible genetic mechanisms for the variability. Two of the mechanisms which have been discussed in the past for changes in protein structure via genetic events appear able to produce large changes by single events. One of these involves chromosomal rearrangements, and specific examples of its involvement are known in the case of the human haptoglobins[25], Lepore hæmoglobins[26], and possibly also in the case of thalassæmias in general[27]. The other mechanism involves the change in amino-acid sequences which is presumed to result from addition or deletion of base pairs from protein structural genes with a consequent shift in the coding frame of reference; the evidence for this type of change is, at present, inferential; but the arguments are extremely persuasive[28,29]. It is suggested here that chromosomal rearrangements involving the γ-globulin structural genes (conceivably also sometimes resulting in a change in amino-acid sequences as a consequence of a shift in the reading frame) are responsible for the variation in the products of the γ-globulin loci in different antibody producing cells. These chromosomal rearrangements are presumed to occur during the somatic cell divisions leading to the mature immune system. Since chromosome pairing and inter-chromosomal crossing over are thought to be rare events in mitosis, the rearrangements are suggested as occurring usually within a single chromatid, or between sister chromatids. (There are ample precedents for somatic events involving intra-chromatid or sister strand crossing over in *Vicia*[30], *Bellevalia*[31] and maize[32,33].) However, it should be noted that the expression of only a single allele in myeloma globulins and Bence Jones proteins could be interpreted as indicating the occurrence of inter-chromosomal crossing over.

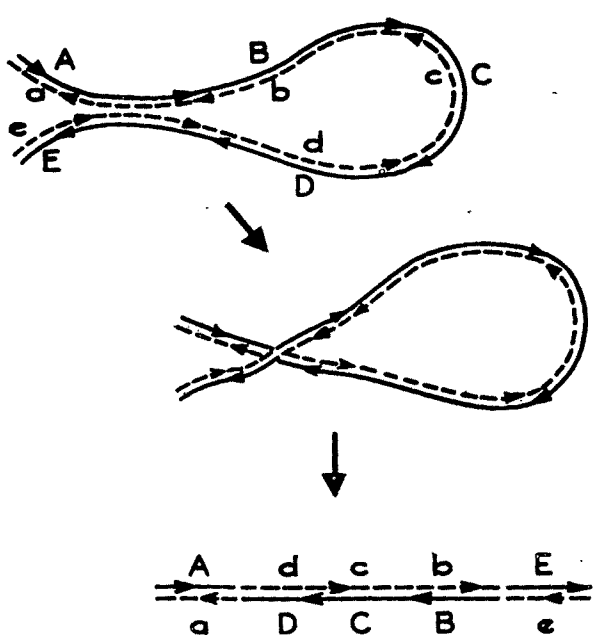
A model γ-globulin gene. In order to illustrate the hypothesis more extensively a specific model will be developed, although it is recognized that others can be conceived. The present model, while perhaps not likely to be proved correct in its details, can nevertheless serve as a basis for the design of experiments to test the overall hypothesis that γ-globulin variability is the consequence of somatic chromosomal rearrangements involving the γ-globulin structural genes. Consideration of the effects of different types of chromosomal rearrangement suggests that the observed variations in γ-globulin structure could be accounted for by rearrangements involving inversions.

Messenger-RNA active in protein synthesis appears to be synthesized in relation to only one strand of the DNA double helix of a protein structural gene[34,35]. This conclusion, based on experimental observations, is supported by theoretical difficulties which make it virtually impossible to reconcile the results of coding experiments[36,37] with the structure of known proteins and the effects of 'point' mutations on proteins if both strands of DNA were copied. If part of the DNA of a protein structural gene is inverted by a chromosomal rearrangement, then, to preserve the sense of direction of the strands, part of the previously uncopied strand will become continuous with the copied strand (Fig. 1). The messenger-RNA copied from the inverted section of the gene will consequently have a changed base sequence (being that

complementary to, and in the reverse order of, the original message), and will instruct the synthesis of a very different sequence of amino-acids from that coded by the same region of DNA before it was inverted. (Cytologically and genetically detected inversions are frequent in many organisms which change the order, but not the expression of the genes in the inverted regions. In these relatively large-scale inversions the relationship between a structural gene in the inverted region and the corresponding indicator (whatever it may be) which determines the active strand of DNA is presumably unchanged. The small-scale inversions considered in this article are assumed to involve regions of DNA for which the active strand is already defined by an indicator outside the inverted regions. It must be stressed, however, that the hypothetical mechanisms for variation in the γ-globulin polypeptides discussed here would not be invalidated if both strands of DNA prove able to dictate the synthesis of messenger-RNA since inversions would change the base sequences in both messages.)

In order for the γ-globulin genes to participate in somatic chromosomal rearrangements of the type illustrated in Fig. 1, without requiring any crossing-over to occur other than in homologous regions of DNA, the genes would have to contain local inverted duplications of base sequences over enough length to permit intragenic synapsis and crossing-over. Since a sufficiently large number of rearrangement products must be possible to generate enough different amino-acid sequences to explain antibody specificity, several pairs of sites where inversion can occur must be present within the gene. This suggests the presence of duplications (without inversion) in the genes. However, some or all of the several pairs of inversion sites could be different.

The number of inverted duplications in a locus needs not be large to obtain sufficient variability. Fig. 2 shows schematically some of the possible rearrangements with only two inverted duplications and two duplications in the original gene. The products of any given rearrangement are available for further rearrangements during subsequent cell divisions, so that the full range of variability could be produced in many different cell lineages.



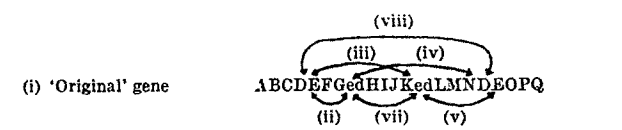


Fig. 1. A diagram representing the consequences of an intra-chromatid inversion. The complementary strands of DNA are represented by solid and dotted lines; their directional senses are shown by arrows. The inversion causes a portion of the 'dotted' strand to become continuous with the 'solid' strand. The capital and small letters are used to represent complementary sequences of bases

(ii) Inversion	ABCDEgfedHIJKedLMNDEOPQ
(iii) Inversion	ABCDEkjihDEgfedLMNDEOPQ
(iv) Inversion	ABCDEFGednmlDEkjihDEOPQ
(v) Inversion	ABCDEFGedHIJKednmlDEOPQ
(vi) Unequal crossing over with sister strand	ABCDEFGedHIJKedHIJKedLMNDEOPQ
(vii) Loss of a small acentric ring	ABCDEFGedLMNDEOPQ
(viii) Loss of a large acentric ring	ABCDEOPQ

Fig. 2. A schematic representation of some of the rearrangement products which are possible in a region of DNA with two duplications and two inverted duplications. Only one strand is illustrated and capital letters and small letters are used to imply base sequences related in the reverse complementary sense (for example, M could be ATGCAA and m would then be TTGCAT)

The observations made on the variation of structure of the type *B* Bence Jones proteins can be accounted for by rearrangements similar to those illustrated in Fig. 2 if the 'original' gene is regarded as a simplified model of an allele at the *Inv* locus. Thus all the rearrangement products would dictate the synthesis of polypeptides with several amino-acid sequences in common (including the *N*- and *C*-terminal sequences) which could account for the immunological characteristics shared by all type *B* Bence Jones proteins. Yet the 'finger prints' of these polypeptides would not be identical.

The observations made on the type *A* Bence Jones proteins are more difficult to reconcile with the control of the structure of these proteins by a single locus. Since no type *A* proteins have been reported as reacting in the *Inv*-detecting systems, they may well be the products of some locus (not yet described) other than the *Inv* locus. This could account for the complete dissimilarity of 'finger-prints' of the *A* and *B* types, but would not solve the problem of the mechanism permitting variation of the *N*-terminal residues of these proteins. Unfortunately no experimental evidence has been published relative to the nature of the signal in naturally occurring messenger-RNA which indicates the commencement of polypeptide synthesis (in synthetic messenger-RNA it is, presumably, the end of the RNA molecule). However, Nirenberg[38] has raised the possibility that the beginning or end of the message, in terms of protein synthesis, might be the result of a region of messenger-RNA which can form a hairpin-like helical structure (since double helical RNA will not stimulate *in vitro* amino-acid incorporation). Such regions would necessarily be coded in DNA by closely linked inverted duplications, and could permit the type of rearrangements (inversions over the *N*-terminal signal) required to account for the variable *N*-terminal residues in the type *A* Bence Jones proteins. Examples of the events envisaged are presented in the next section.

An examination of the reasonableness of the model. The reasonableness of any model involving inversions can in part be assessed by inspection of the base triplets which code for specific amino-acids. Lists of these triplets are increasing so rapidly at the time of writing that I have used a list presented in a lecture by Dr. Severo Ochoa in Madison during February. This tentative list (of 41 coding triplets) was based on the work of the groups of Nirenberg and Ochoa, and on an analysis by Jukes[39] of data derived from amino-acid substitutions observed in mutant proteins. Eighteen of the twenty amino-acids can be coded by triplets which in their reversed complementary form also code for amino-acids (even with the present incomplete list). It is perhaps not coincidental that two amino-acids (glutamic acid and serine) which each constitute more than 10 per cent of many γ-globulins can be coded by their reversed complements (AAG and CUU respectively). Suitable hydrogen-bonding sites in the final γ-globulin polypeptides could thus be maintained, even after the occurrence of inversions, if these two hydro-

Fig. 3. A hypothetical model for part of a structural gene for a γ-globulin polypeptide to illustrate some of the consequences of intra-chromatid inversions and sister strand crossing over. The DNA of the original gene is shown at the top, and below are the messenger-RNA sequences copied from the active strand before and after different re-arrangements of the structural gene. The corresponding amino-acid sequences are shown below each type of messenger-RNA. The regions involved in the rearrangements are shown in italics. The sense of direction of the nucleic acid strands is indicated by arrows which also represent segments of the molecules with sequences of bases not written *in extenso*. Details of the intra-chromatid crossing-over event leading to the inversion III–IV are shown in Fig. 4

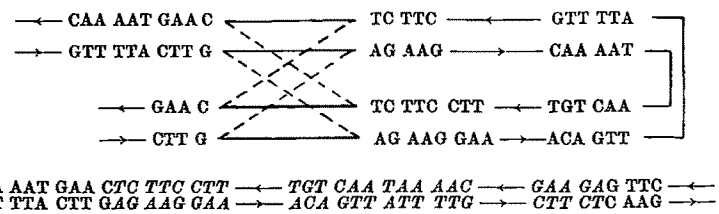

Fig. 4. Details of a typical intra-chromatid crossing-over event leading to an inversion (the III–IV inversion of Fig. 3). Homologous regions of DNA are assumed to be necessary for the occurrence of synapsis and crossing-over. The dotted lines indicate the continuity of the strands after the crossing-over. The inverted region is italicized

gen-bonding amino-acids were coded by the triplets indicated.

There is convincing independent evidence for the existence of local inverted duplications in DNA of the type here suggested as involved in the γ-globulin loci. Thus the recent work of Spencer *et al.*[40] on the helical hairpin-like nature of soluble-RNA, and the observations of Goodman and Rich[41] that soluble-RNA is synthesized in relation to specific regions of DNA leave little doubt of the occurrence of regions of DNA with quite small-scale inverted duplications of about 40 base pairs length.

As a final enquiry into the reasonableness of the model involving inversions, an attempt has been made to present in detail in Figs. 3 and 4 a hypothetical structural gene for a γ-globulin polypeptide of the kind involved in the Bence Jones proteins of type *A* with examples of the effects of different rearrangements on the final amino-acid sequences (including the *N*-terminal residue). It must be stressed that inversions over the *N*-terminal signal leading to a change in the *N*-terminal residue would not be excluded if some specific sequence of bases codes for the *N*-terminus. The necessary crossing-over could still be achieved if the reversed complement of the whole or part of the sequence of bases corresponding to the 'beginning of message' sign occurred in the active strand of the amino-acid coding region of the gene. On the other hand, if the reversed complement of part or all of the 'beginning of message' sign (whatever its nature) does not occur in the amino-acid coding region of the gene, then inversion over this sign is not likely to be possible. The *Inv* genes may be of this type since the *N*-terminal residue of type *B* Bence Jones proteins shows no variation. Rabbit γ-globulins also have one polypeptide with a fixed *N*-terminal sequence[42], (NH_2)Ala.Leu.Val.Asp.Glu—, and so probably inversions cannot occur over the *N*-terminal end of the gene controlling this polypeptide. In more general terms, it is clear that for a part (or the whole) of a gene to be susceptible to inversion it must be flanked by inverted duplications.

Considerations of this type suggest that some of the unusual properties of the alleles at the *Gm* locus can be interpreted in terms of the location of inversions within these genes. Thus in heterozygotes (Gm^a/Gm^b) the Gm^b allele is expressed in myeloma globulins with only about one-fifth the frequency of the Gm^a allele, and in six negroes (Gm^{ab}/Gm^{ab}) all the myeloma globulins were ($Gm(a+\ b-)$ (ref. 18). If that portion of the genes Gm^b and Gm^{ab} which controls the $Gm(b+)$ phenotype contains an inverted duplication of some other part of the gene (or is between two inverted duplications) then its expression would be susceptible to suppression by inversion. If the $Gm(a+)$ phenotype were determined by part of the gene outside any inverted duplications it would not be suppressed by the rearrangements.

In the preceding discussion the tacit assumption has been made that the duplications in the γ-globulin structural genes involve integral numbers of amino-acid coding units (triplets). If they do not, then some rearrangements will cause a change in the sequence of the resultant polypeptide of the type discussed by Crick *et al.*[28]. This raises the interesting possibility that type *A* as well as type *B* Bence Jones proteins could in fact be determined by the *Inv* locus, but that in the *Inv* genes the inverted duplication suggested as coding for the 'beginning of message' sign involves a non-integral number of coding units. Absence of inversion over the *N*-terminal sign would lead to the fixed *N*-terminal amino-acid (aspartic acid) of type *B* Bence Jones proteins and be accompanied by reading of the message with one frame of reference, but an inversion over this region would change the *N*-terminal amino-acid and be accompanied by reading of the message with a different frame of reference (corresponding to type *A* Bence Jones proteins). Ability to react in the *Inv*-detecting systems and with antibodies against type *B* proteins would be lost as a consequence of the completely changed amino-acid sequence dictated by the new frame of reference.

Experimental tests of the hypothesis. The most direct and realizable method for testing the hypothesis would seem to be the determination of amino-acid sequences in a number of Bence Jones proteins. The relationships between the sequences obtained from a given structural gene before and after different rearrangements have occurred are illustrated in Fig. 3, and permit some predictions to be made. A prerequisite of the occurrence of many rearrangement products is the presence of several inverted duplications within the gene, but until the genetic code is completely known these will be difficult to detect by amino-acid sequence studies. However, there may also be duplications within the gene, which would be detected in the Bence Jones proteins as repeated amino-acid sequences (for example, Glu.Gly.Ser is repeated in Fig. 3) unless the duplications involve a non-integral number of coding units. After an inversion, whole sequences will be changed *en bloc* but will still be between unchanged sequences when integral numbers of coding units are involved (for example, Glu.Pro.Ser—Val.Tyr.Cys.Thr—Arg.Glu.Gly.Ser becomes Glu.Pro.Ser.Leu—Leu.Gln.Ilu.Asn—Glu.Gly.Ser). The position in the whole polypeptide of these new sequences will be variable depending on the particular inversion (cf. the positions of Leu.Gln.Ilu.Asn after the four inversions illustrated). Inversions over the *N*-terminal signal of different lengths are presumed necessary to give type *A* Bence Jones proteins with different *N*-terminal residues. The distance from the *N*-terminus to the position where common sequences occur should consequently differ in such proteins (cf. the position of the common sequence Leu.Gln.Ilu.Asn in the two inversions II–IV and II–V), as should the lengths of the common sequences. These predictions could be tested by sequence determinations, particularly of the *N*-terminal regions, on type *A* Bence Jones proteins with different *N*-terminal residues.

General observations. If the present hypothesis of somatic rearrangements in the structural genes for the γ-globulins has any validity, it is possible that this type of change is involved in other sorts of differentiation. Certainly the types of mechanism here discussed, which permit an initially fixed genotype to be changed by somatic events occurring during development (cf. Nance[27]), should be considered in relation to differentiation in general.

I thank Drs. James F. Crow and Walter E. Nance for their suggestions during the preparation of this manuscript. The work was supported by grants from the

U.S. National Institutes of Health (*GM*–08217) and the National Science Foundation (*G*14240).

OBITUARY

Prof. B. B. Bevan-Baker

Bevan-Baker, who died on July 1 at the age of seventy-three, was a man of rich and varied talents whose early promise of the highest scientific and mathematical achivement was tragically frustrated by the ill-health that beset him from middle life. But until illness enforced an early retirement, he gave distinguished service to the University of London and Royal Holloway College.

Bevan Braithwaite Baker was born in 1890; in ultimately adopting the surname Bevan-Baker he was merely acquiescing in a usage of many of his friends. He entered University College, London, in 1906 and graduated in physics at the age of nineteen. He then did research on crystal structure in metals in London and in Munich; in some of this work he was associated with his contemporary, E. N. da C. Andrade (now Professor), to whom he evidently owed his introduction to the subject. Baker's interests then changed and he took London degrees in mathematics in 1912 and 1914. During the First World War he served with the Friends' Ambulance Unit in Italy, this being in accordance with his Quaker upbringing. On his return, he was from 1918 until 1920 assistant in pure mathematics in University College. From 1920 until 1924, Baker was lecturer in mathematics in Edinburgh under E. T. Whittaker. This was the time of his fruitful mathematical activity. His main work was a series of papers on periodic orbits, but he wrote also on such varied topics as the hypergeometric function, the path of an electron in the neighbourhood of an atom, and an extension of Heaviside's operational calculus. Baker was elected a Fellow of the Royal Society of Edinburgh in 1921; he gained a D.Sc. at Edinburgh in 1923 for a much extended account of his dynamical work. He was secretary of the Edinburgh Mathematical Society from 1921 until 1924.

From 1924 until 1944, Baker was professor of mathematics in the University of London and head of the Department of Mathematics in Royal Holloway College. He played a big part in the general affairs of the College in peace and in war. He was called on to serve for two consecutive three-year terms as a Staff Governor, a most exceptional procedure. During his headship, the undergraduate school of mathematics flourished greatly and its students gained more than a proportionate share of high honours in University of London examinations. A few of these women mathematicians began postgraduate work at Royal Holloway College before going on to research elsewhere, and they now hold distinguished positions in universities in Britain and overseas. Although Baker was disappointed at not doing more to develop a postgraduate school, this was actually the beginning of what has now become a well-known research centre (now taking both men and women students). But no account of Baker's time at Royal Holloway College should omit mention of Miss Marion Pick, a graduate of the College and a lecturer throughout Baker's term of office, who supplied the immediate stimulus to the students who were to make a career in mathematics and who also kept the Department in full operation during Baker's illnesses.

Baker was the most unselfish of men and bestowed innumerable kindnesses on colleagues and students. At one time he was an impressive figure of immense girth. This was because of thyroid trouble and after this was cured he became over-slim. During the rest of his working life he had a series of illnesses until his doctors ordered his retirement at the early age of fifty-four. Baker was denied the stamina to do much research work after joining Royal Holloway College. His name appears as joint author with E. T. Copson of *The Mathematical Theory of Huygens' Principle* (Oxford, 1939), but again his health caused his contribution to be far less than he wished.

Music was Baker's ruling passion; he was a pianist of the highest class for a non-professional, and he played various other instruments and took part in operatic and other singing. Family opinion in his youth had dissuaded Baker from following music as a profession, so it was a wonderful consolation for him for many years to share in and to enrich the musical life of Royal Holloway College. In 1918 Baker married Margaret Barbour of Edinburgh, sister of the distinguished geologist, G. B. Barbour of Cincinnati. She sustained him in every way until her death in 1961. Until then he had enjoyed his retirement in improved health but his health declined again after that. Baker is survived by four of his five children.

W. H. McCrea

NEWS and VIEWS

C.S.I.R.O. Division of Soils: Mr. J. K. Taylor

MR. J. K. TAYLOR will retire in December 1963 as chief of the Division of Soils, Commonwealth Scientific and Industrial Research Organization, Australia. Mr. Taylor graduated in agriculture at the University of Sydney in 1920 and became demonstrator in agricultural chemistry at that University. In 1921 he was awarded a Walter and Eliza Hall research fellowship for postgraduate research in soils and plant nutrition at the Universities of Sydney and California. He obtained his M.Sc. degree at the latter University in 1923, his B.A. degree at the University of Sydney in 1924, and was appointed lecturer in agricultural and dairy bacteriology at Hawkesbury Agricultural College, New South Wales. In 1927, Mr. Taylor was appointed to the Division of Soils Research of the Council for Scientific and Industrial Research, the forerunner of C.S.I.R.O., where he undertook the first soil surveys conducted by the Council. Mr. Taylor was closely associated with his chief, Prof. J. A. Prescott, in building up the Division and expanding its soil survey activities. He also played an important part in the establishment of regional laboratories in various parts of Australia so that the work of the Division could be carried out more effectively. Mr. Taylor was appointed deputy chief of the Division in 1944 and chief in 1947. Since then, the scope of the Division's research has been greatly increased and there are now strong research groups concerned with the chemistry, physics, and microbiology of soils, and with clay mineralogy, pedology and soil survey. Mr. Taylor has been closely associated with many aspects of the development of soil science in Australia. He played a leading part in the formation of the Australian Society of Soil Science and was its president during 1958–60.

Prof. E. G. Hallsworth

PROF. E. G. HALLSWORTH, professor of agricultural chemistry at the University of Nottingham, has been appointed to succeed Mr. Taylor. Prof. Hallsworth graduated at the University of Leeds in 1936 and became assistant lecturer in agricultural chemistry at that University. He obtained his Ph.D. from Leeds in 1939 and in 1940 went to Australia as lecturer in agricultural chemistry in the University of Sydney. While at Sydney he developed investigations on pedogenesis and fertility of soils and published a series of papers with his students, dealing with particular soils of New South Wales ranging from the alpine humus soils to the gilgais. He built up a substantial knowledge of these soils during this period and was able to make a critical review of shortcomings in the great soil group system of classification when applied to Australian soils. In 1950 he returned to England to become professor of agricultural chemistry in the University of Nottingham, where he took a leading part in building up one of the most flourishing university departments of agriculture in Britain. At Nottingham, Prof. Hallsworth undertook research on the micro-element nutrition of legumes. He and his colleagues demonstrated recently that cobalt has a part to play in nitrogen fixation by nodulated clover. During 1960–61 Prof. Hallsworth revisited Australia as visiting professor of soil science in the University of Western Australia.

Biochemistry at Ghana: Prof. C. B. Coulson

DR. C. B. COULSON, at present head of the Department of Biochemistry and Biophysics of the Arthur D. Little Research Institute, near Edinburgh, has been appointed to the recently instituted chair of biochemistry, nutrition and food science in the University of Ghana at Legon. Dr. Coulson, born in Nottinghamshire and educated at the Riley High School, Hull, and High Pavement School, Nottingham, graduated with honours in chemistry in Prof. R. D. Haworth's Department in the University of Sheffield in 1949. His research on plant proteins and amino-acids in Prague gained him the Doctor of Natural Sciences of the Charles University in 1952. Work in the same field gave him an M.Sc. degree (University of Sheffield), while his work on biochemical aspects of triterpenoidal saponins led to the award of a Ph.D. of the University of Wales. In 1952, as a junior research fellow of the then Institute of Seaweed Research, he examined the proteins and amino-acids of marine algae. In 1955, after military service, he joined the research staff of the Department of Agricultural Chemistry (now Department of Biochemistry and Soil Science) under Prof. W. Charles Evans at the University College of North Wales, Bangor. He continued work there as an Imperial Chemical Industries Research Fellow and as a lecturer in biochemistry and soil organic matter. His research interests extended to farm animal biochemistry and soil biochemistry as well as triterpenoidal saponins. In 1960 Dr. Coulson took up his present post and has been concerned with research on wheat gluten, anti-tubercular glycopeptides of milk whey (with Prof. T. Fujiwara, of the University of Osaka) and the industrial utilization of peat humic acids, both at the Institute and for O.E.C.D,

The Department of Biochemistry, Nutrition and Food Science, in the Faculty of Agriculture of the University of Ghana, is to be associated with the Food Technology and Marketing Investigation Unit (F.A.O.), which is to be set up with a grant of nearly two million dollars spread over five years from the United Nations Special Fund and the Government of Ghana. The main task of the Department will be to develop the output of specialists in the fields covered by the Department and to extend research in biochemistry, nutrition and food science within the context of West Africa.

The National Council for Technological Awards

THE sixth report of the National Council for Technological Awards covers the year ended March 31, 1963, in which 927 Diplomas in Technology were conferred, making a total of 2,019 since September 1958 (Pp. 59. London: The National Council for Technological Awards, 1963). At the end of the year, 7,310 students were following courses leading to the Diploma and the number of first-year students had risen to 2,715. Some 350 industrial organizations provided industrial training for students on whom the Diploma was conferred during the year. Over the past three years the proportion of college-based first-year students has increased from 17 per cent to 31 per cent in engineering courses, and from 53 per cent to 71 per cent in other technologies. Three awards were made of Membership of the College of Technologists. Among appendixes to the report is a list of 117 courses, at 28 colleges, which are now recognized by the Council as leading to the Diploma in Technology.

Effective Use of Outside Research Facilities

A BROCHURE, issued by the Battelle Memorial Institute, outlines the procedures which are being used successfully by some corporations to establish a close working relationship with outside research laboratories such as the Battelle Memorial Institute (*A Practical Plan for the Effective Use of Outside Research Facilities*. Pp. 8. Columbus, Ohio: Battelle Memorial Institute, 1963). The benefits both to the corporation and the research institute resulting from such a relationship are outlined and the

booklet indicates concisely the characteristics and value of contract research for industry. Emphasis is laid on the importance of determining the areas in which outside research facilities promise to be most useful and also the facilities, experience and talent which the research institute can apply in these areas. The way in which these two are related may vary considerably. A further booklet, *Group Research*, also issued by the Battelle Memorial Institute, describes the nature of the group research projects conducted by the Institute during more than thirty years, their conduct and administration and the general advantages of such research, as well as the contribution which a research institute can offer to this type of co-operative research. Stress is laid on the value of the objective approach which such an institute can bring, and it is claimed that outside research organization with experience of group research can define and analyse problems effectively, nominate potential research approaches and formulate programmes which take account of technical, economic and social aspects.

Training Guide, 1963

The *Training Guide, 1963*, published by the Royal Institute of Chemistry, gives details of qualifications and courses, grants and scholarships, and firms sponsoring sandwich courses for students in chemistry (Pp. ii+36. London: Royal Institute of Chemistry, 1963. 2*s*. 6*d*.). Lists of universities and colleges offering full-time degree courses in chemistry as well as of technical colleges offering full-time, sandwich or part-time courses leading to qualifications in chemistry or applied chemistry are also included.

Index to Current Periodicals received in the Library of the Royal Anthropological Institute

The library of the Royal Anthropological Institute receives more than 470 current periodicals connected with every branch of anthropology. Now an index to these periodicals is being prepared under various headings—physical anthropology, archæology, cultural anthropology, ethnography and linguistics (1, Part I; January–March, 1963. Subscription 40*s*. per annum, four parts). Copies can be obtained from the Librarian of the Royal Anthropological Institute, 21 Bedford Square, London. The production of periodical literature has so increased in recent years as to make it almost impossible to keep track of what has appeared. The *Indexes* of the Royal Anthropological Institute will prove of real use to students in the various branches of anthropology and will meet a very pressing need.

Black Soils of India

The *regur* soils (meaning sticky black earth) of India, also called black cotton soils, have excited a good deal of interest among soil scientists, because of their extent, economic importance and characteristic properties. A recent publication summarizes the information available (66 references) and is illustrated by several maps and photographs showing the location, vegetation and profiles of these soils (*Black Soils of India*. By S. P. Raychaudhuri, B. B. Roy, S. P. Gupta and M. L. Dewan. Pp. iv+47. New Delhi: National Institute of Sciences of India, 1963). They cover an area of about 800,000 sq. km. of the Deccan peninsula. The climate is monsoon, the average annual temperatures being 20° C in December and 30°–35° C in May; the average rainfall is between 500 and 1,000 mm, mostly from June until September. The natural vegetation is tropical dry deciduous and tropical thorn forest, the dominant species being *Anogeissus latifolia*, *Terminalia tomentosa* and *Acacia catechu*. The parent material of the soils is mainly Deccan trap, alluding to the step-like aspect of basaltic rocks, of the Cretaceous period; the black soils are found not only on the volcanic plateau but also on transported material derived from the trap and on other formations of basic character. The typical black soil on flat or gently undulating ground may be several metres deep without zoning; it is shallower and not so dark in colour on slopes. It is slightly alkaline, low in organic matter—the percentage of carbon being about 0·5—but contains, on the average, 50 per cent clay and has a high cation exchange capacity saturated mainly with calcium and magnesium. The chief clay mineral is montmorillonite. It shows great expansion and shrinking on wetting and drying; the aggregates are stable, the permeability is good. Cotton, jowar, ground-nut and wheat are the important crops, and also sugar cane if irrigation is possible. These soils are placed in the world group of black soils of the tropics and subtropics ('grumusols').

Announcements

Sir Edward Playfair, chairman of International Computers and Tabulators Ltd., has been appointed president of the British Computer Society in succession to Mr. R. L. Michaelson. Sir Edward is a governor of the Imperial College of Science and Technology, a member of the boards of Westminster Bank Ltd., Westminster Foreign Bank Ltd., and Glaxo Laboratories Ltd., and is also a member of the Royal Fine Arts Commission. He has held various Government positions.

The "Polarmeeting 1963" of the German Society of Polar Research will be held in Karlsruhe during October 6–9. Further information can be obtained from Karl-Heinz Tiedemann, 23 Kiel, Eckernforder Strasse 1.

A one-day symposium on "Food Supply and Nature Conservation" will be held at the Cambridgeshire College of Arts and Technology on November 2. Further information can be obtained from Dr. R. I. B. Cooper, Cambridgeshire College of Arts and Technology, Collier Road, Cambridge.

A meeting of the Photoelectric Spectrometry Group on "Reflectance Spectroscopy" will be held at the Imperial College of Science and Technology, London, on October 25. Further information can be obtained from the Honorary Secretary, the Photoelectric Spectrometry Group, Unicam Instruments Ltd., York Street, Cambridge.

The Technicon Instruments Company's third annual symposium, entitled "Automated Chemical Analysis and Automated Analytical Techniques", will be held during November 5–6 at the Royal College of Surgeons, Lincoln's Inn Fields, London. Further information can be obtained from the Technicon Instruments Co., Ltd., Hanworth Lane, Chertsey, Surrey.

The Institute of Physics and the Physical Society has announced that its 1964 Exhibition of Scientific Instruments and Apparatus will be held in the Halls of the Royal Horticultural Society, Vincent Square, London, S.W.1, during January 6–9, 1964. The 1965 Exhibition will be held in the first week of April in the Manchester College of Science and Technology.

An international Solar Symposium will be held at the University of Sydney, under the auspices of the Australian Commonwealth Scientific and Industrial Research Organization and the University of Sydney, during November 12–15. Its purpose is to review present-day solar research, to discuss plans for the forthcoming solar cycle and to consider the problems of postgraduate training in astrophysics. Further information can be obtained from the Organizing Committee, Solar Symposium, Radiophysics Division, C.S.I.R.O., University Ground, City Road, Chippendale, Sydney, N.S.W., Australia.

Erratum. In the seventh paragraph of the article entitled "Decomposition of Alkali Metal Nitrates by Light Ions of Kilovolt Energy", by Dr. S. R. Logan, which appeared on p. 369 of the July 27 issue of *Nature*, "34 eV/amp" and "10 eV/amp" should read 34 eV/Å and 10 eV/Å respectively.

LIQUID METALS

A CONFERENCE was held at the Fulmer Research Institute, Stoke Poges, to bring together as many as possible of the workers concerned with the experimental study of liquid metals. The meeting was convened with the help and encouragement of Dr. B. R. T. Frost, of the Metallurgy Division of the Atomic Energy Research Establishment, Harwell. Prof. J. D. Bernal (Birkbeck College, University of London) acted as chairman.

Dr. J. E. Enderby (University of Sheffield) directed attention to the considerable variation found in the absolute value of the resistivity (ρ) (at constant volume) and the way in which it varies with temperature. The resistivities of sodium and potassium are strictly proportional to the absolute temperature; in contrast, divalent metals, zinc, cadmium and mercury, have a negative temperature coefficient. Values of the resistivity ratio ($\rho_{liquid}/\rho_{solid}$) vary between 1·45 and 2·2; a trend exists through the alkali metals and the noble metals which is related to the energy-gap across the Brillouin zone boundary. The change in thermoelectric power across the melting-point has the value 0 for sodium, silver and gold, but for copper it is as high as 9·5. Hall coefficient measurements give the free electron value. Thus for metals such as zinc and cadmium the coefficient changes sign and becomes negative on melting.

Mr. B. W. Mott (Harwell) dealt with a modification of the Hildebrand rule which can be used to predict immiscibility in alloy systems. A parameter is calculated, the Mott number, which depends on the atomic volume, heat of evaporation and electronegativity of each of the components, together with the melting-point of the more refractory metal. There will be immiscibility if the Mott number is lower than the smallest Pauling valency. The main difficulty involves the selection of electronegativity values, those given by the Gordy relationship predict immiscibility in 84 per cent of the 886 systems examined.

Simple X-ray diffraction patterns, obtained from pure molten metals such as sodium and copper, can be contrasted with those from metals where structure can be shown to exist, gallium, bismuth and tin. In the case of liquid tin Mr. B. R. Orton (Fulmer Research Institute, now at Brunel College of Advanced Technology) was able to show that, by careful calculation of the radial distribution function, two atomic species are present in the melt. One can be identified with covalent grey tin, the other forms the random matrix of metallic white tin. For other metals which occupy the *B* groups of the periodic table it is possible to show that the participation of the covalent bond increases with valency. Diffraction patterns from liquid alloys also show structure. In the gold–tin alloy system a dominant structure is found which corresponds in composition to the solid-state electron compound, Au_3Sn. Other alloy systems show structure (copper–indium, copper–tin, silver–indium, gold–gallium and gold–indium). At the same valency electron concentration, different alloys of the above group show similar diffraction patterns.

Dr. H. N. V. Temperley (Atomic Weapons Research Establishment, Aldermaston) proposed that previous machine calculations, based on the rigid sphere model of a liquid, should help in the understanding of solidification. There is, however, very poor agreement with approximate theories in the high-density region. In addition to more detailed calculations, a new field is opened in Bernal's statistical geometry. The two-dimensional case is being investigated first. Two models of the lattice type are considered, rigid square and rigid rod. The first has the restriction that the presence of a molecule at one point on a square lattice prevents the occupation of the four neighbouring points. This model shows a transition between a completely disordered arrangement at low density and an alternating structure at high density. Transitions from one to the other are found to be first-order transitions in the Ehrenfest sense. This is in qualitative agreement with the results for rigid spheres. In the second model the molecules are identified with pairs of neighbouring points, no lattice point being occupied more than once. This model is more satisfactory for mathematical study, though only very general results are obtained.

Dr. P. A. Egelstaff (Harwell) described how cold neutrons can be utilized in the study of diffusion in liquids. Most of the existing theories consider the diffusion process to be either gas-like or solid-like. If these models are applied to the viscosity and diffusion data on liquids it is concluded that liquid diffusion is unlike either of the two starting points. A new model is formulated that involves the co-operative action of a number of atoms, termed 'globules'. Predictions are made, using this model, which are confirmed by experimental results, thus giving direct evidence of co-operative units in liquid metals.

Another model was proposed, by Dr. J. Wilson (University of Birmingham), in which the liquid is visualized as consisting of atomic clusters having a definite structure in a matrix of randomly arranged atoms. A state of dynamic equilibrium exists between the clusters and the matrix. The structure of the clusters need not be the same as that of the corresponding solid. The lifetime of the clusters, composed of 50–150 atoms, may be one or two orders greater than the relaxation time of the liquid. This model provides an explanation of the minimum value found in the plot of viscosity against composition for certain eutectic alloys. The minimum represents a transition point between the liquid alloy being dominated by one or other of the pure components. Other published data confirm this model

Describing the inadequate state of the theories of thermodynamics when applied to the explanation of the nature of the bonds in alloy formation, Dr. S. Ll. Leach (Royal School of Mines, University of London) suggested an alternative procedure. The thermodynamic properties must be considered with other physical properties (resistivity and X-ray diffraction measurements) to give a complete picture. He quoted, as an example, the gold–tin alloy system, where all this information is available. From the X-ray measurements it is deduced that there are two types of bond, the short-range covalent and long-range metallic bond. The published resistivity measurements support this view. A maximum, which is independent of temperature, is found at the composition Au_3Sn. It seems possible that as the temperature of the liquid is raised the covalent bonds break down and the electrons released just compensate for the increase in thermal scattering. The success of this approach has led the Royal School of Mines to embark on a programme of experimental measurements of a number of physical properties on one or two selected alloy systems.

The chairman, Prof. J. D. Bernal, concluded the meeting with some general comments on the nature of pure liquids and alloys. The transition from solid to liquid could, he said, be associated with higher vibration-levels, changes in geometrical configuration, greater disorder, lower co-ordination number and lower mean lattice energy. For ideal liquids, machine calculations have emphasized the importance of the short-range forces. If these forces only are taken into account then a discontinuity is found which corresponds to the solid to liquid transition. To understand the liquid to gas transition the

behaviour of argon above the critical point is important. There is no single fluid phase but two distinct states of matter even though there is no visible discontinuity.

Commenting on the models of Dr. Egelstaff and Dr. Wilson, Prof. Bernal suggested that the presence of globules could be detected by the use of small-angle scatter and an estimate of their size obtained from viscosity measurements.

Turning next to alloys, Prof. Bernal put forward the idea that they could be considered as emulsions and cited as evidence the presence of the γ-phase in alloys of copper, silver or gold with zinc. In this phase the atoms are distributed at random over the lattice sites. However, the electron compound found in the gold–tin alloy system could be the cause of the structure observed in the X-ray diffraction patterns.

B. R. Orton

RADIOACTIVE CHEMICALS, LABELLED COMPOUNDS AND RADIATION SOURCES

FOR most purposes, particularly in engineering and radiotherapy, where the radiological properties of radioisotopes are of paramount importance, it is generally sufficient to refer to the tabulated physical data given in Part 1 of *The Radiochemical Manual* for a suitable choice of radioactive material. However, in the case of radioactive tracers for use in the biological sciences, chemical technology and related fields, the purity, chemical stability and the characteristic behaviour of the isotopes as radioactive chemicals are often the decisive factors, and for these Part 2 of the *Manual**, which has recently been published and which deals with the chemical aspects of radioactive materials, must be consulted.

The range of radioactive chemicals is very extensive, and Part 2 has therefore been limited to a number of articles on selected topics likely to be useful to users of radioactive tracers. The examples referred to are drawn largely from the practical experience of the scientific staff at the Radiochemical Centre at Amersham. The contents of Part 2 consist of three sections, dealing with the sources of radioactive chemicals, some characteristic features of the chemicals, and notes on labelled compounds of the elements carbon, hydrogen, sulphur, phosphorus, iodine and chlorine.

The first section contains four chapters in which the distinctive features which affect the manufacture of radioactive reagents are outlined. Radiological protection and remote handling frequently limit the types of chemical manipulation which can be carried out. The half-life of the isotope is the important factor in the organization of supply and distribution, and the chemical scale of manufacture which rarely exceeds one gram is a unique feature. The distinction between primary isotopes and labelled compounds is clearly drawn and the various methods of preparation are explained. Isotopic labelling and its wider implications, the synthesis of labelled compounds by chemical and biological methods and some of the unresolved problems such as the isotopic labelling of natural products by biosynthesis, are also discussed.

Chapters 5–7, which form the second section, are concerned with the concepts of purity and its determination, instability, and the behaviour of minute quantities and dilute solutions of radioactive chemicals. The final six chapters in the third section refer individually to compounds of each of the six elements which are most commonly concerned in tracer experiments. Carbon-14, which emits only β-particles, is produced by means of a reactor in adequate quantities and at high specific activity, and, since it has a half-life of 5,760 years, it is a most favourable tracer isotope. It has been used for the intensive study of biochemical processes and has now virtually displaced the stable isotope carbon-13 and the short-lived (20 min) radioactive isotope carbon-11. Tritium-labelled compounds are now second in importance to carbon-14 compounds in biochemical tracer work, but tritium is not used as a hydrogen tracer but as an accessory tracer for a carbon atom or a molecule or a molecular fragment. Tritium is available in quantity and high specific activity (up to 29 c./m.amp) and its half-life of 12·3 years is conveniently long.

Sulphur-35 is the only practicable label for sulphur atoms. Its half-life is 87·2 days, and although it can be produced by direct neutron irradiation, it is better extracted as sulphate at high specific activity from neutron-irradiated potassium chloride. The main groups of chemical in which sulphur-35-labelled compounds are of interest are listed in the *Manual*. Phosphorus-32 is relatively easy to prepare. Its half-life is 14·2 days and its main applications are in inorganic fertilizers, nerve gases, systemic insecticides, and plasticizers. Iodine-131 is in abundant supply from irradiated tellurium or from fission products, but its short half-life prevents stockholding of iodine-labelled compounds. Other isotopes of iodine, iodine-132, iodine-125 and iodine-124, are also available. Chlorine-36 has a long half-life of $3{\cdot}03 \times 10^5$ years and is a pure β-emitter of medium energy. Its production is expensive and its specific activity is low, less than 4 mc./m.amp. Chlorine, however, is an important industrial chemical and therefore chlorine-36 has valuable applications. It is also in many ways an ideal radio-isotope for use in the teaching of practical chemistry.

Part 2 of the *Manual* concludes with thirteen tables of synthetic routes to labelled compounds, a glossary of terms used, and numerous references to published work relating to the topics discussed and the tables. For details of the products, radioactive chemicals and radioactive sources, and services provided by the Radiochemical Centre the reader is referred to the catalogue. *Radioactive Products*†, available on request from the Centre.

RESEARCH INTO TECHNICAL EDUCATION

THE report of a working party, with Prof. A. V. Judges as chairman, set up at the second session of a conference on June 6, 1961, presided over by Dr. Dunsheath, and attended by representatives of the University of London, the Regional Advisory Council for Technological Education (London and Home Counties), local authorities, technical colleges and research institutions, has now been published under the title *Research into Technical Education**. The working party was charged, *inter alia*, with considering priorities in research in this field and, apart from the specific proposals for research which are detailed, the report gives in its introduction an admirable survey of the present position and of the

* *Research into Technical Education: Report of a Working Party.* Pp. 34. (London: The Regional Advisory Council for Technological Education. London and Home Counties, 1963.) 5*s*.

several authorities and institutions that are already active. Appended to the report, moreover, are notes on relevant activities of the National Foundation for Educational Research and the British Association of Commercial and Industrial Education, details of projects already in progress in the London colleges, of the two educational research projects in the Department of Mathematics at the Hatfield College of Technology and of the Nuffield research projects at the Birmingham College of Advanced Technology and at Brunel College.

Although the working party does not lose sight of its main concern—the technical colleges—this general survey is of considerably wider interest and the comments made are probably valid over a fairly wide field of secondary and of higher education. More research is obviously being carried out into technical education than is generally realized. However, the research position is scrappy and disjointed, and the working party believes that the present investment rate is ahead of intelligent application. In particular, besides greater availability of statistics, in the institutional field the clearing services need overhauling to facilitate awareness of what is happening in cognate fields. The working party found great difficulty in discovering the annual investment in the development of research into technical education, but if the planning of research into specialized training within industry is to be absorbed into the prime costs of industry and marketing, it suggests that assistance is needed in four ways.

First, established posts are necessary in the centres of higher education in the faculties of arts, education or applied science. Secondly, research units need to be established in universities, colleges of advanced technology, and other institutions, with an independent budget, and headed by specialists who may or may not be members of the academic staff. Thirdly, there is room for specific enquiries in any establishment, industrial or academic, with the use of a research studentship or *ad hoc* grant. Fourthly, development might be promoted within the National Foundation for Educational Research of the existing division concerned with research and information on technical education.

All this needs manpower and suitable recruitment, and the spread of incentives are at the heart of the whole problem of launching large-scale projects into new territory. The working party particularly stresses the need for more specialized workers in educational psychology, statistical methods, and the design of educational experiments, economic analysis, and sociology. It lists the topics for research in five broad groups, but makes no attempt to indicate a desirable priority. The groups cover entry to technical education and training, methods of teaching and training; relation between technical education and industrial and commercial training; problems of a broad scope, such as forecasting needs for technical personnel, aspects of public examinations, economics of the technical education; and comparative studies of technical education.

Even the titles of the broad groups of projects listed in this report indicate the implication of such research in other fields of education. The working party considers the question whether the developing situation calls for national supervision by some body after the style of the Medical Research Council. It is firmly of the opinion that, whether or not such surveillance is desirable, existing organizations must accept the need for close co-operation and the pooling of information and must agree on some form of clearing-house facilities. The Ministry of Education and the Scottish Education Department, the Ministry of Labour, the National Foundation for Educational Research, the Scottish Council for Research in Education, the National Advisory Council on Education for Industry and Commerce, the British Association for Commercial and Industrial Education are all concerned in one way or another, and the universities, local education authorities and organizations of teachers also have interests to develop. All these in coming together should attempt some more formal and structural form of co-ordination.

The working party considers that the initiative in securing closer co-operation should be taken by the Government, and points out that the case for creating a national council or grants committee, with powers to handle funds, to consider the direction of policy and to report to the Privy Council through a Minister, would be stronger if considerable sums from the national exchequer became available for disbursal among institutions engaged with research projects. Such a step would not, however, remove the need for much closer co-operation generally; it reiterates that the lead in developing new work must be taken by the National Foundation, the universities, the technical teacher training colleges, industrial firms and associations, local education authorities, and associations of principals and teachers in technical colleges, regional advisory councils, and the technical colleges and teachers themselves. It sees hopeful signs in the creation of the intelligence and research organization of the Ministry of Education, and the increased support given to the National Foundation for Educational Research. Furthermore, it suggests that the universities through their Departments of Education may be able, in the next quinquennium, to direct more of their resources into problems of technical education and to encourage postgraduate research in this field. This is important in view of the great need for research workers, and the working party suggests that conditions for the award of academic qualifications as a result of educational research should be broadened to give postgraduate workers in this field an incentive comparable with that of postgraduate workers in scientific and technical research.

MODIFICATION OF THE WEATHER

THE great economic potential of successful weather control led the United States Congress in 1958 to ask the National Science Foundation to launch a full-scale investigation of this exciting field of modern meteorology. Within the Foundation, a Weather Modification Research Programme has been developed as an integral part of the more inclusive Programme on Atmospheric Sciences, which required funds amounting to 6,615,000 dollars during the fiscal year ending June, 1962. Of this sum, 1,340,000 dollars were set aside to support weather modification research under a system of grants and contracts from the Foundation to research groups at university, Government and other laboratories.

The one major technique in use for weather modification is only fifteen years old. This is 'cloud seeding', that is, the introduction, into a cloud, of material calculated to have an effect on the constituent cloud particles. Certain clouds and types of fog can be modified; and, under certain conditions, rainfall can be somewhat augmented and hail discouraged. The possibilities merit further careful investigation.

A summary of progress made in the United States National Weather Modification Programme up to 1962 appears in a report[1] issued by L. J. Haworth, director of the National Science Foundation. Work has been concentrated on basic studies into the nature of cloud phenomena, on the study of known cloud-seeding methods, and on the investigation of other methods of local modification of clouds. The last-mentioned investigation includes methods of changing ascending or descending air currents, or of

changing the electrical field of the cloud by, for example, hanging miles of electrified wire across canyons in North Mexico. The Foundation also sponsors investigations in atmospheric dynamics and the general circulation, and these may make significant contributions to the investigation of weather modification over large regions; and on the large scale may eventually determine what kinds of man-made influences can affect large weather patterns, and climate. Large-scale weather modification is, by nature, international in scope, and co-operation and co-ordination is essential between some twenty nations at present making research efforts in weather modification.

The report also contains the results of a Rand Corporation study group[2], briefed by the Foundation to analyse past and present attempts at modifying weather and to consider suggestions for achieving weather control; the Rand group emphasized the importance of co-ordination of theory with mathematical models of the atmosphere for the electronic computer, with laboratory models and other laboratory studies, as well as with field observations. Modification may be possible through an understanding of the physical processes involved within a cloud; or of the air currents associated with it; or of the major synoptic weather systems and the general circulation. Various associated investigations should be encouraged, for example, palæoclimatology may be helpful in revealing causes of the great climatic changes of the past. The various effects of man-made atmospheric pollution should be studied, for example, carbon dioxide, and the pollution of the upper atmosphere by space vehicles and rockets.

Theoretical studies are aided by large electronic computers for solving the equations of motion of simplified models of the atmosphere. The use of such models permits the research worker to test the effect of suggested methods of weather modification, for example, the effect of damming the Bering Strait; or of removing ice from the Arctic Sea; of controlling evaporation over the ocean by covering the surface with a chemical film; or of changing the radiation balance over snow surface by a coating of carbon black; or of finding the most favourable circumstances in which a small modification might act as a 'trigger mechanism' to set off a larger modification. Calculations may also be made on small-scale diurnal phenomena, for example, the behaviour of fog and stratus cloud at a coast line. Even smaller scale atmospheric motions within clouds may be studied, for example, to show collision frequencies of cloud droplets and possible changes due to modified electric fields.

Besides including further computer studies, the future plans of the Foundation again involve such projects as cloud-seeding research and the effects of 'seeding' on hurricanes, research on cloud electrification and research on the control of the hydrological cycle through control of evaporation.

Space technology and radiation studies may even lead to control of the radiation balance by altering the composition of the upper levels of the atmosphere, or by introducing artificial cloud layers in suitable places. The report concludes that the time for rapid progress appears to be at hand with a variety of new theoretical and practical tools, provided that the project continues to attract well-trained and talented man-power. A WORKING MODEL OF THE MECHANICAL ESCAPEMENT IN SU SUNG'S ASTRONOMICAL CLOCK TOWER

By Prof. AUBREY F. BURSTALL, W. E. LANSDALE and P. ELLIOTT
Department of Mechanical and Marine Engineering, University of Newcastle upon Tyne

In 1960, Drs. Needham, Wang Ling and Price published a detailed description of the mechanism in the Chinese astronomical clock tower built for the Emperor by Su Sung in A.D. 1092 (ref. 1), in which the mechanical power for driving the mechanism was provided by a large wheel eleven feet in diameter mounted with its axis horizontal, the wheel carrying thirty-six scoops equally spaced around its circumference. The wheel moved intermittently as the result of water flowing into the scoops in turn, the weight of water in a full scoop being sufficient to tilt a weighted lever obstructing the movement of the wheel, and the water poured out of each scoop after it had passed the weighted lever. The wheel was brought to rest after the passage of each scoop by stops worked by latches while the wheel was in motion. The authors claimed that the apparatus was of great importance to the history of mechanical clockwork since it provided a 'missing link' between the water clocks and clepsydra of antiquity and the first mechanical escapements developed in the West during the Middle Ages. They suggested: "that the whole design is reminiscent of the anchor escapement of the late seventeenth century, since the driving wheel is a scape wheel and the pallets are inserted alternately at two points on its circumference separated by 90° or less . . ." In a footnote on the same page they observe, "the more subtle aspects of Su Sung's mechanism will not reveal themselves until a working model has been constructed. We may hope that such a task will be undertaken . . ."

The present authors took up this challenge and have now produced a working model (their Mark III model: the first two models, though they operated successfully, did not meet all the requirements specified in *Heavenly Clockwork*) which appears to meet the requirements specified in the text and, furthermore, incorporates a component essential to the operation of the mechanism and described by the translators simply as "some kind of star-shaped gadget", the function of which they were unable to guess. We have named it "an interrupter cam".

Our own reading of the text of *Heavenly Clockwork* together with experiments we have made with two earlier models lead us to believe that Su Sung's escapement was composed of eight distinct elements each one of which was essential for its operation.

They are shown diagrammatically in Fig. 1 and were: (*A*) The 'scape' wheel carrying thirty-six scoops equally spaced around the periphery. As the wheel turned it was arrested as each scoop reached the horizontal diameter where it was filled with water until the wheel moved on for the next scoop to be filled after tilting the weighted lever (*B*). Each scoop carried a projecting pin at one side for operating the escape latch (*C*). (*B*) A weighted lever hinged near the centre provided with a counter poise at one end and a forked end for stopping the scoops at the other. A pin between the fork of this lever operated the interrupter cam (*G*) just before the wheel was stopped by the buffer and caused to recoil. (*C*) An escape latch connected by the chain (*D*) to the overhead stopping lever (*E*) which carried a buffer stop at one end. This buffer stop normally rested between two adjacent pins at the

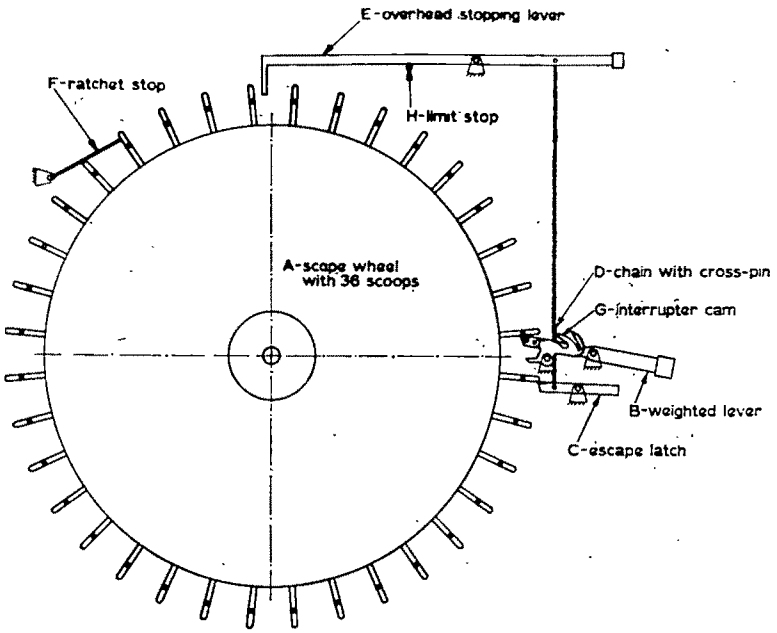

Fig. 1

top of the wheel. When the escape latch operated, the buffer stop was raised and lifted over the next pin to rest again in the space between the next two pins. (*D*) A chain connecting the escape latch (*C*) to the overhead stopping lever (*E*) so that during the first part of the motion of the wheel the buffer stop was lifted whereas when the next pin approached it did not operate, thus allowing the upper stop (*E*) to function and bring the wheel to rest. The model (and probably the original) was provided with a cross-pin fixed to the chain and, as the weighted lever tilted, its movement inserted the interrupter cam below the pin so that the lower part of the chain was lifted, causing the escape latch to miss the next pin on the wheel just before the recoil, though the same pin was able to operate the escape latch again after the wheel had been stopped, recoiled, and come to rest (Fig. 2). (*E*) The overhead stopping lever carrying a buffer at one end and weighted so that this buffer remained in position with the lever resting on the limit stop (*H*) except when the chain was pulled down by the escape latch to allow the next pin to pass the buffer. (*F*) A ratchet stop near the top of the wheel to prevent the wheel from recoiling too far when its forward motion was arrested by the buffer. The parts of the mechanism were disposed so that one of the pins rested on this ratchet as each scoop was being filled. (*G*) An interrupter cam to lift the lower end of the chain and thus the escape latch during the later part of the wheel's motion, so that during this time the escape latch could not function and therefore the buffer stop remained in position and was able to operate as a stop. The interrupter cam was probably turned by a pin projecting from the weighted lever as in the model and as it turned the lower part of the chain was lifted by the cross-pin on the chain on to the cam, thus raising the escape latch so that it missed making contact with its pin during the later part of the motion of the wheel. (*H*) A limit stop on which the overhead stopping lever could rest at all times except during the short periods when the chain was pulled down by the escape latch causing the buffer to rise over the pins one at a time.

We have not previously come across this combination of motions in any mechanism nor have we seen any reference to it in historical or horological publications. It is surprisingly sophisticated for its period, but it most probably represents the system used on the original celestial globe of Su Sung for the following reasons:

(1) All the eight components of the escapement are depicted on the original Chinese woodcuts in Su Sung's book.

(2) All the eight components of the escapement are necessary for its functioning. If any are removed it will not work.

(3) All but the last two components—the cam and the stop are described in the translation of the original Chinese script of Su Sung.

(4) The similarity of the "star-shaped gadget" (Fig. 3*a*) shown on the Chinese illustration, and the interrupter cam (Fig. 3*b*) the shape of which was determined by the geometrical requirements of the escapement supports the belief that the "star-shaped gadget" was in fact an interrupter cam made to perform this function.

(5) The position where the cam is shown on the illustration is the place where it must be located since it must lift the chain and be operated by the weighted lever.

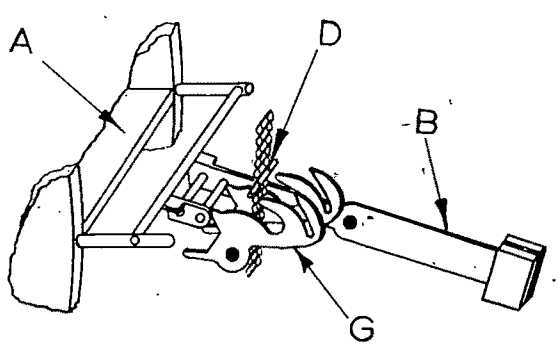

Fig. 2

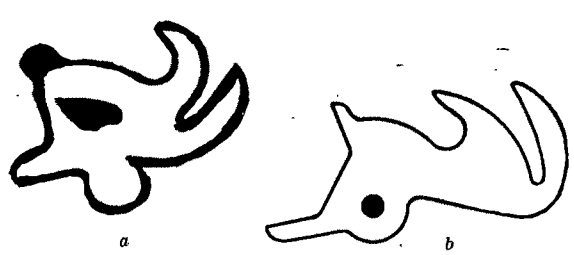

Fig. 3

Until we had discovered the function of the interrupter cam and added it to the assembly the most baffling feature of the mechanism (as described in *Heavenly Clockwork*) was that the upper stop carrying the buffer could never stop the wheel, since it was lifted clear of the wheel every time the wheel was due to be stopped, that is, the buffer could not 'buff'.

SLOW EXPANSION OF A PLASMA COLUMN WITHOUT THE APPLICATION OF A MAGNETIC FIELD

By Dr. P. AVIVI, N. BEN-YOSEF, F. DEUTSCH and Dr. A. S. KAUFMAN*
Department of Physics, Hebrew University of Jerusalem, Israel

THE device *Maya* was built with the view of creating and investigating a plasma originating in the positive column of an arc discharge, during and subsequent to the rapid ejection of the discharge-tube walls. A suitable magnetic field would be applied to confine the exposed plasma and the neutral gas streaming from the positive column into the surrounding vacuum region would be absorbed by a titanium getter. *Maya* may be regarded as the complement of confinement devices using injection of plasma into a magnetic field.

During the testing of *Maya* without an applied magnetic field, it was observed that electrostatic probes, situated outside the initial boundary of the positive column in hydrogen, responded to the arrival of electrons only after a delay of about one to two milliseconds from the commencement of ejection. In addition, if two probes were set at the same radial distance from the discharge tube, then the one farther from the exposed column responded to the arrival of electrons a perceptible fraction of a millisecond later than the probe situated more closely. Similar effects were observed for positive-ion collection.

This article is a preliminary account of these observations. If it is assumed that the probes do not perturb the plasma motion, the results indicate that the expansion rate of the plasma column into vacuum is very slow—about 10^4 cm sec^{-1}.

The device *Maya* comprised three main sections—the plasma chamber, the ballistic section and the buffer (Fig. 1).

The plasma chamber was a stainless steel cylinder of length 40 cm and inner diameter 16 cm. Concentrically disposed was a cylindrical discharge tube formed from either duralumin or stainless steel, with an insulating lining of inner diameter ranging from 2·7 cm to 3·1 cm according to circumstances. Before ejection, the discharge tube was seated in the cup, which was lined with 'Teflon'. In this position, the discharge tube and plasma chamber were both electrically insulated and hermetically sealed from each other. The two vessels were evacuated separately and the pressure in the space between them was between 2×10^{-4} torr and 1×10^{-3} torr. No attempt was made to attain a still lower pressure.

Arc discharges were produced in a continuous stream of hydrogen at a pressure of 3×10^{-2} torr and the gas flow was maintained during ejection. No undue care was taken as to the purity of the hydrogen. A hot cathode was used and the anode consisted of a disk of molybdenum attached to an exposed stem of stainless steel. The cathode and plasma chamber were fixed at earth potential and the potential difference between the electrodes during the running of the arc was in the range from 80 V to 150 V for most of the runs. The discharge current prior to ejection ranged from 0·25 to 0·77 amp. It was maintained during ejection and, in general, increased at a steady rate during ejection to a value which was about 30 per cent greater than before ejection commenced.

* In former publications, A. S. Kaufman was known as S. Kaufman.

After the arc was struck, axial ejection of the discharge tube followed. The ejection was arranged by firing a projectile in the ballistic section so that the momentum would be transferred to the discharge tube via the neoprene membrane. The mechanical buffer arrested the motion of the discharge tube after it had left the plasma chamber. The speed of ejection was measured by timing the passage of the discharge tube between two phototubes prior to the retarding action of the buffer. The average speed of ejection was in the range from $1{\cdot}7 \times 10^3$ cm sec^{-1} to $2{\cdot}5 \times 10^3$ cm sec^{-1}. The signal from the first phototube also acted as a trigger for the oscillographs.

Electrostatic plane probes were situated at different levels and radii in the space between the vessels so as to determine the location of the plasma during ejection. The probes, formed from tungsten rods of diameter 1 mm, were sheathed in glass to the extremity. Each probe was connected directly to a separate dry-cell battery and thence to an oscillograph, with a resistor of 10 kΩ in parallel to earth. One of the probe mounts on the first level could be used for a second timing arrangement in which a photomultiplier detected the light from the arc

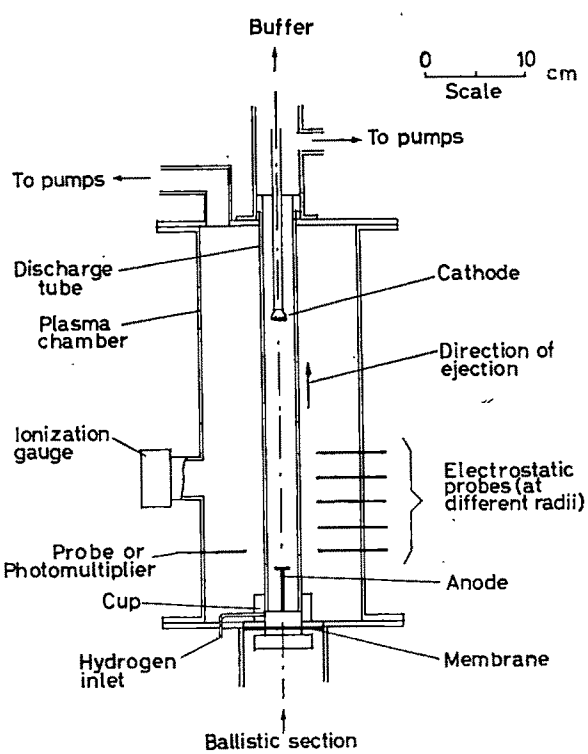

Fig. 1. Longitudinal section (schematic) of *Maya*

when the end of the discharge tube reached this level. Rapid changes of gas pressure in the plasma chamber were recorded by an ionization gauge situated at the height of the fourth level of probes and at a distance of 7 cm outside the wall of the plasma chamber. The changes in ion current were fed into a fast-rise amplifier and thence into an oscillograph.

In a short account, the observations can best be presented by selecting a typical run. Fig. 2 depicts the probe signals where probes 1, 3 and 4 were set at a positive potential of 145 V and probe 6 at a negative potential of 40 V, all with respect to the cathode. The location of the probes is shown in Table 1. The first three probe traces show that a time in excess of 1 msec elapsed before any overall collection of electrons took place. A period of several milliseconds then ensued before these signals reached some steady value (not shown in Fig. 2). In addition, there was a distinct delay in response of 0·3 msec between probes 3 and 4 for the run in question. The result of many runs was that when the probes were set either at the same level or at the same radial distance, the more distant probes responded to the arrival of electron current later than those situated closer to the exposed column, even when the probe positions and potentials were altered. In many cases, but not apparently in all, a pip made its appearance just prior to, or with, the main signal (see the trace of probe 4). The time of current collection was reckoned from the appearance of this pip or from the clear bend in the trace when the pip was absent.

Table 1. Computed Speeds of Plasma Expansion (Run 34)

Probe	z (cm)	r (cm)	Method A $10^{-4}\ V_p$ (cm sec^{-1})	Method B $10^{-4}\ V_p$ (cm sec^{-1})
4	7·4	1·4	0·9 (probes 1,4)	0·6
1	9·9	3·8		0·8
3	12·4	1·5	1·3 (probes 3,4)	0·9
6	7·4	5·5	not calculated	

z, Vertical distance from probe level to the bottom of the plasma chamber.
r, Radial distance from collecting surface of probe to the external wall of the discharge tube.
V_p, Speed of plasma expansion.

A number of runs were also performed with positive-ion collection. The initial delay in response and the delay between probes were evident as for the collection of electrons. It is significant that the positive ions reached one probe earlier than the electrons reached a second probe placed on the same level and at the same radial distance—in one particular run, by as much as 0·3 msec. The collection of positive ions by probe 6 is shown in Fig. 2, but the amplifier sensitivity in this case was too low to indicate exactly the start of current collection.

The ionization gauge was used to measure the response time for the neutral gas. In a typical case, it responded to the fastest neutral particles 1·4 msec prior to the start of the electron collection on a probe at the first level.

When the photomultiplier was connected, it was possible to determine the time delay in the trigger signal with respect to the commencement of ejection. For the run in question, this time was 0·4 msec with a maximum possible error of $\binom{+0\cdot2}{-0\cdot0}$ msec. Thus, in Fig. 2, the recorded initial delays in probe response were shorter than the real delays by this time. It was also possible to locate the position of the discharge tube at the time of the response of the probes. For the same run, the length of exposed column between the cup and the discharge tube was 1·2 cm when the nearest probe (No. 4) began to respond.

All the results quoted here were obtained in the absence of an externally applied magnetic field. On the application of a steady longitudinal field of several hundred œrsteds, the delay between probes was increased—in one case, to 0·8 msec.

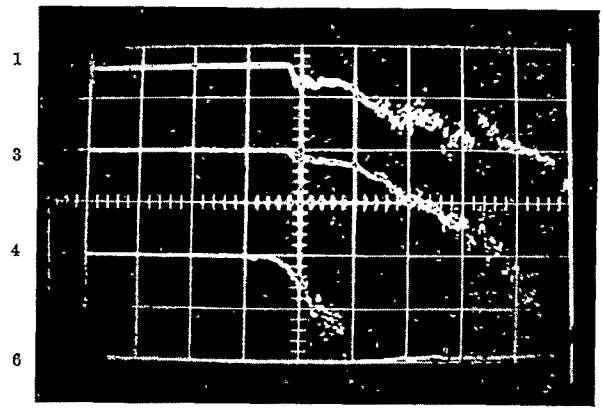

Fig. 2. Probe signals as a function of time (run 34); abscissa, each main division is 0·5 msec; ordinate, for probes 1, 3, 4, each main division is 2 V, for probe 6, each main division is 0·5 V; positive current is in the positive direction; discharge current (before ejection), 0·50 amp; arc voltage, 150; average velocity of ejection, $2{\cdot}0 \times 10^3$ cm sec^{-1}

The principal features of these observations will now be interpreted. The electrons and ions detected by the probes must have originated in the arc discharge. The possibility of a glow discharge between the anode and the plasma chamber can be excluded because the potential difference between them was less than the normal cathode fall required to maintain a glow discharge. It is thus evident that during ejection the plasma column expanded from the boundary of the discharge tube into the space between the two vessels.

The speed of plasma expansion will now be computed by two different methods. Basic to both are the following assumptions—the probes do not influence the rate of plasma expansion, there is no accelerated motion of the plasma, expansion takes place along a straight line, and that it displays circular symmetry.

In method A we also assume that the speed of expansion is independent of the direction of expansion. Then from the delay in response between a pair of probes it is possible to compute speeds of expansion as given in Table 1. It is not essential to know exactly when the plasma started to expand. The speeds are not substantially altered whether the plasma began to expand as the tube left the cup or even when the tube reached a level 2 cm from the cup. The fact that there is no single-valued speed of expansion from different pairs of probes, and this is clearly confirmed by many other runs, may be due to the incorrectness of the assumptions. For example, the speed of expansion is indeed a function of direction, or the plasma possesses accelerated motion in the longitudinal direction. The results examined are compatible with the latter possibility and also indicate that the speed of expansion in the radial direction is less than that in the longitudinal direction.

Method B is based on the time that elapsed before each individual probe responded. At this stage, it is not possible to determine exactly the moment when the plasma was capable of streaming from the discharge tube into the plasma chamber. We arbitrarily assume that the plasma began to move when the tube cleared the cup. In addition, it is supposed that there was no delay between the arrival of electrons at a probe and the recording of the probe signal. This method yields speeds of a similar order of magnitude to method A but somewhat lower (Table 1). The acceleration of the plasma in the longitudinal direction is also demonstrated.

When the probe traces were recorded with high amplification, a small fluctuating signal was discernible during the delay until electron collection at the knee of the trace occurred. If we assume that this signal was genuinely due to the arrival of electrons of the most probable velocity, then their concentration was about 10^7 cm^{-3} as compared with an estimated concentration of at least 10^9 cm^{-3}

at the wall of the positive column before ejection. A concentration of 10^7 cm^{-3} must be regarded as an upper limit.

In conclusion, from an examination of some twenty runs, the initial delay in electron collection and the delay between probes both indicate the same result, namely, a speed of plasma expansion of about 10^4 cm sec^{-1}. Further support is derived from the observation that a time of several milliseconds elapsed from the start of electron collection until a steady signal was attained. The computed results are consistent with a model in which the plasma, after leaving the discharge tube, is accelerated in the longitudinal direction. However, in view of the preliminary nature of the results, some other model of expansion cannot be excluded.

Little[1] investigated the rate of expansion of a highly ionized plasma in mercury vapour into a tenuous and feebly ionized region. A measured velocity of about 10^5 cm sec^{-1} agreed with the calculated wave velocity for the propagation of electro-acoustic waves in the plasma. In the case of hydrogen, the calculated wave velocity would be about 10^6 cm sec^{-1}, which is much greater than the measured speeds of expansion in the present work.

The evidence for the slow expansion of the plasma column rests solely on the probe signals. Such slow motion in the absence of an external magnetic field has been unknown hitherto, so it is natural to suspect the probes. If a probe were to introduce some delay in collection, then a case could be made against method *B* but not against method *A*, since identical probes were used. Furthermore, in one run during which the probes responded at different times as usual, there was afterwards a break in the discharge current which was not maintained. The collection of current by all the probes then ceased simultaneously.

At this stage it would be premature to offer an explanation of the slow expansion: However, it is certain that it is not an aerodynamic effect related to the ejection; the neutral particles reached the ionization gauge much more quickly than the charged particles reached the probes. It is possible that the effect is associated with the stability of the plasma sheath and that some form of electrostatic confinement retards the motion of the plasma.

Measurements with electrostatic probes show that the plasma originating in the positive column of an arc discharge expands into vacuum during the removal of the discharge-tube walls at a speed of about 10^4 cm sec^{-1}. The results may be of importance for work related to the confinement of plasmas from material walls. The account is only preliminary and in future work it will be important to confirm the slow rate of expansion by an independent method of measurement (for example, microwaves) and to determine its dependence on such parameters as the discharge current, the gas and its pressure, and the velocity of ejection.

CROSS-STRATIFICATION AND PALÆOGEOGRAPHY OF THE LOWER GREENSAND OF SOUTH-EAST ENGLAND AND BAS-BOULONNAIS, FRANCE

By J. NARAYAN

Sedimentology Research Laboratory, Department of Geology, University of Reading

THE Lower Greensand, in which the Hythe and Folkestone Beds are the principal members, is a shallow marine deposit dating from the Lower Aptian to Lower Albian. The principal British outcrops lie in the Isle of Wight, southern Dorset, Wiltshire, the Weald, East Anglia. The Weald outcrop continues into the Bas-Boulonnais.

Kirkaldy[1] described the deposit as 'shallow marine' with the vertical and lateral variations in lithology characteristic of the 'belt of variables'. According to Casey[2] the Lower Greensand was deposited in two main basins, one to the north and one to the south of the London ridge; but present work on the cross-stratification suggests that this may not have been the case in Folkestone Beds times.

Cross-stratification is present throughout the Lower Greensand, but in places has been partly destroyed by organisms and growth of ferruginous concretions. Two main types of cross-stratification are encountered in the Hythe and the Folkestone Beds: (1) planar, (2) trough, as defined by McKee and Weir[3]. In thickness the units vary considerably from a few centimetres to about three metres. This variation may be due to unevenness of the floor. In the Folkestone Beds the trough cross-stratification is associated chiefly with the finer sands, and the planar type with the coarser sands. Deformed cross-stratification[4] is present locally. Other sedimenta-

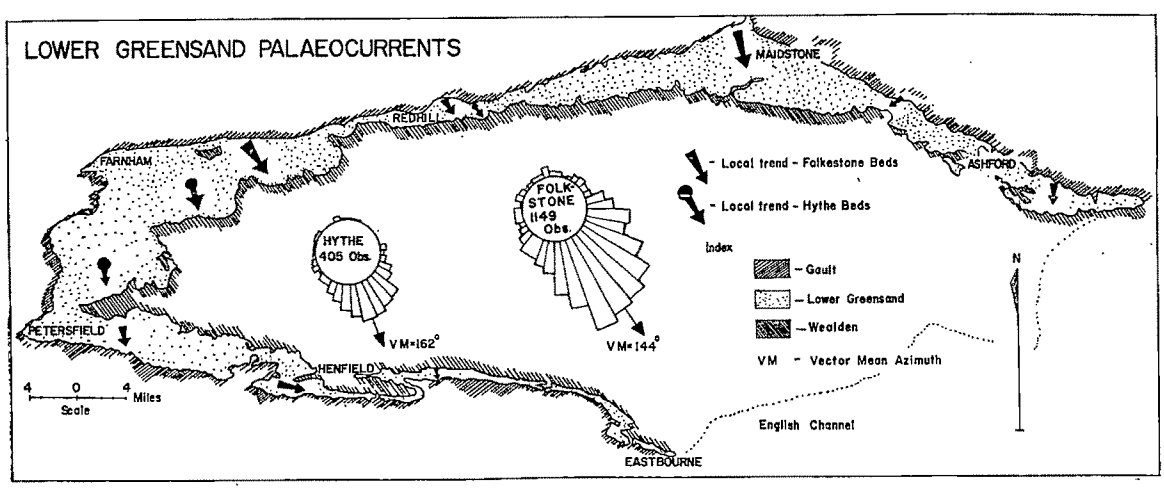

Fig. 1. General current pattern in the Hythe and the Folkestone Beds. Each arrow shows the general trend of the current in that locality. The size of the arrow, however, is irrelevant. The rose diagrams show the general distribution for the whole area with the vector means

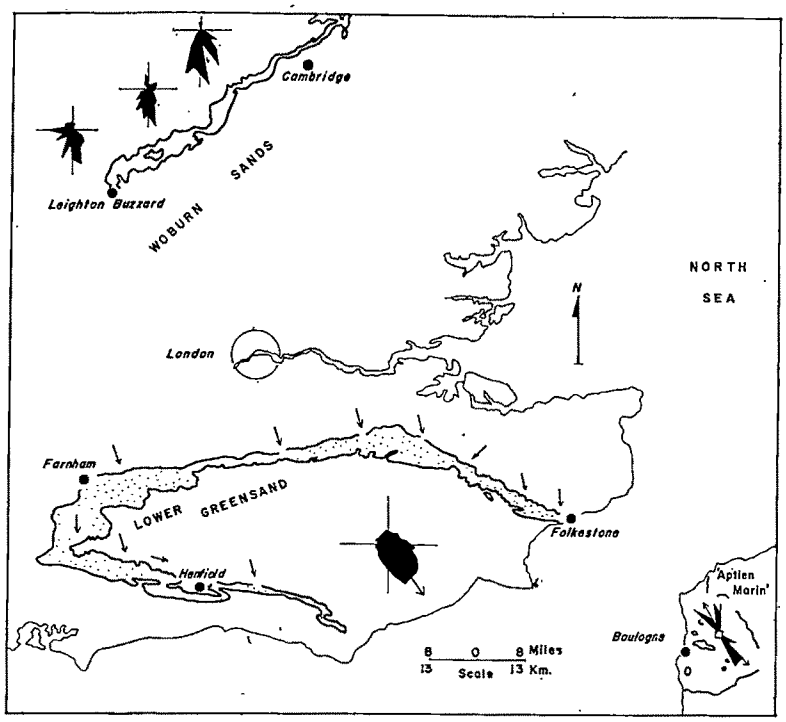

Fig. 2. Comparative current pattern of the Folkestone Beds, the Woburn Sands (after ref. 10) and 'Aptien marin' of Bas-Boulonnais, France. Arrows indicate vector means

tion structures include channelling, burrowing and small-scale ripple marks. There are two main types of channels: (1) those which were eroded and filled simultaneously, and (2) those which were filled later. Burrowing as described by Middlemiss[5] is very common. The calcareous sandstones of the Hythe Beds show parallel laminations defined by the variations in glauconite content. These laminations are almost horizontal, indicating a slacker water environment. A slower rate of sedimentation is supported by the churned nature of the sediment as pointed out by Middlemiss[5]. The equivalent horizon in the Isle of Wight is Group VI (ref. 6) which is also churned up. Hence quieter sedimentation appears to have set in over a wide region during this particular period.

Cross-stratification dip directions in the Hythe and the Folkestone Beds were measured in a statistically randomized manner. Four hundred and five observations were made in the Hythe Beds. The vector mean azimuth[7] is 162°. Fig. 1 gives the general distribution of the current pattern. The vector magnitude (L) is 73·4 per cent, which is well below 10^{-20} probability level (Rayleigh test). The maximum dip attained by the foresets is 38°. In general, however, their inclination is less than 20°, and almost horizontal near Petworth.

Eleven hundred and forty-nine cross-stratification dip directions were measured in the Folkestone Beds. The vector mean azimuth was calculated for the whole area (144°) and for each locality (Fig. 1). The vector magnitude is 65·1 per cent, which is well below 10^{-20} probability-level (Rayleigh test). The maximum cross-bed thickness observed was about 3 m and the maximum foreset dip 38°.

In the Bas-Boulonnais 94 observations were made in the 'Aptien marin'. Two main current directions prevail (Fig. 2). The vector mean azimuths are respectively 133° and 330°.

Analysis of the cross-stratification data (Figs. 1 and 2) shows that the palæocurrents were essentially constant from the north-west throughout the period. The cross-bedded units are associated with the silt bands tending to thicken towards the bases of the units. When traced upstream, they appear to split into several bands and then disappear within the units. This indicates a rhythmically pulsating current, perhaps tide-generated as indicated by Allen[8]. Study of Recent sand bodies in the North Sea by Stride[9] has revealed a definite pattern in their distribution resulting from currents always running parallel to the coastline. Applying this to the Lower Greensand of the Weald and Bas-Boulonnais suggests a north-west–south-east coastline. Schwarzacher[10], studying the Woburn Sands in East Anglia, found almost the same current direction (Fig. 2). It may well be that the London ridge did not exist during the deposition of the Folkestone Beds and that the southern and northern sedimentary basins were directly linked. Perhaps, the so-called London ridge carried only a thin veneer of sediment, later stripped off evenly.

Wood[11] has studied the heavy detrital minerals of the western part of the Weald and found an increase in kyanite from the Hythe to the Folkestone Beds. Whereas he cites Armorica as a possible source, the present work shows that the sediments last drifted from the north.

Further study of the detritals and the sedimentary structures of the Lower Greensand should reveal more precisely the regional environment.

I thank Prof. P. Allen, Mr. J. R. L. Allen and Dr. R. Casey for their advice.

ANALYSIS OF PHOTOSYNTHETIC REACTIONS BY THE USE OF MONOCHROMATIC LIGHT

By Dr. KUNIO TAGAWA, HARRY Y. TSUJIMOTO and Prof. DANIEL I. ARNON
Department of Cell Physiology, University of California, Berkeley

EXTENSIVE work with algal cells in several laboratories, reviewed recently by Smith and French[1] and by Witt *et al.*[2], has led to a now widely held view that photosynthesis involves the co-operation of at least two pigment systems, chlorophyll *a* and an 'accessory' pigment system such as chlorophyll *b*, each pigment activating a separate photochemical reaction which is essential to the overall process. However, these investigations with intact cells were concerned mainly with enhancement of quantum yields and with spectral changes in cellular constituents following activation of specific pigments, and have yielded little biochemical evidence correlating component reactions

of photosynthesis with specific pigment systems. To quote Smith and French[1], "such evidence comes primarily from action spectra for various measurable effects", but because of the experimental difficulties involved "the complete accounting, on a quantitative basis, for the detailed shape of action spectra in terms of the absorption spectra and of the diverse functions of the several pigments involved remains a hope for the future".

The aim of this investigation was to correlate, experimentally, pigment function with those partial reactions of photosynthesis which have been isolated at the sub-cellular level (in chloroplasts) and have thus been freed from the structural and functional complexity of whole cells. Sub-cellular photosynthesis was sub-divided into its component reactions by fractionating chloroplasts[3] and by altering their biochemical environment[4]. Preliminary experiments in this laboratory[5,6] attempting to correlate this biochemical analysis with effects of monochromatic light were encouraging. This article reports on the photochemical activity of isolated chloroplasts that were illuminated by monochromatic light at a wave-length (663 mμ) which is absorbed by both chlorophylls *a* and *b*, and at a wave-length (708 mμ) which is absorbed by the chlorophyll *a* pigment system but not by chlorophyll *b*.

Biochemical Analysis of Photosynthesis by Chloroplasts. Before reporting on the photochemical activity of chloroplasts in monochromatic light, it will be useful to summarize their photochemical reactions in white light. Apart from oxygen evolution[7] (Hill reaction) and total synthesis of carbohydrates[8,9], the photosynthetic capacity of isolated chloroplasts is now known to include photosynthetic phosphorylation[8] (photophosphorylation), that is, a light-induced synthesis of adenosine triphosphate. Once the discovery of photophosphorylation in spinach chloroplasts had been extended to photosynthetic bacteria[10], algae[11] and various higher plants[12], it became clear that this conversion of radiant energy into the chemical bond energy of adenosine triphosphate is an essential component of all photosyntheses in Nature[13–15].

At first, adenosine triphosphate was the sole product of photophosphorylation, but later a second type of photophosphorylation was discovered, again initially in spinach chloroplasts[16] and afterwards in photosynthetic bacteria[17] (compare also refs. 18 and 19), in which the photoproduction of adenosine triphosphate was coupled with the photoreduction of pyridine nucleotide. The new reaction, named non-cyclic photophosphorylation (which in chloroplasts is also coupled with oxygen evolution), and the older type, renamed cyclic photophosphorylation[20], jointly constitute the photochemical phase of photosynthesis that generates the two components of assimilatory power (adenosine triphosphate and reduced pyridine nucleotide) which together drive the dark, enzymatic conversion by chloroplasts of carbon dioxide to carbohydrate[21,22].

This biochemical partition of sub-cellular photosynthesis into a light and dark phase was corroborated by a separation, in a physical sense, of the photosynthetic apparatus in chloroplasts. Chloroplasts were fractionated into a water-insoluble green portion (grana) which contained the photosynthetic pigments that are concerned with the photochemical phase and a non-green, water-soluble fraction which contained the enzymes involved in the dark conversion of carbon dioxide to carbohydrate[23]. Photosynthesis by chloroplasts was next carried out in two successive steps[3]: first, the photochemical phase which, apart from oxygen, yielded the assimilatory power, and second, the chemosynthetic phase in which the assimilatory power was used in the dark to convert carbon dioxide into carbohydrates.

Our recent investigations of the photochemical phase of photosynthesis in chloroplasts have centred on ferredoxin[24–27]. The water-soluble extract of chloroplasts contains not only the enzymes of carbon assimilation[3,23] but also a protein, ferredoxin, which has been identified as a key intermediate in photophosphorylation. (Chloroplast ferredoxin has also been described as the methemoglobin-reducing factor[28], the TPN-reducing factor[29], photosynthetic pyridine nucleotide reductase[30] (PPNR) and the red enzyme[31]. The ferredoxin nomenclature[24,32] used here is based on the recently found chemical and functional similarities in what appears to be a family of ferredoxins in bacteria[33] and in photosynthetic cells[24].)

Ferredoxin is the most electro-negative constituent isolated so far from the photosynthetic apparatus of green plants[24]. When ferredoxin is photoreduced[25] by grana, its subsequent fate determines whether cyclic or non-cyclic photophosphorylation takes place. Non-cyclic photophosphorylation results if reduced ferredoxin is reoxidized by triphosphopyridine nucleotide (a dark reaction mediated by a flavoprotein enzyme[24,31,32], ferredoxin-triphosphopyridine nucleotide reductase[34,35]) and cyclic photophosphorylation results if reduced ferredoxin is reoxidized not by triphosphopyridine nucleotide but by a bound chloroplast component of the cyclic photophosphorylation system[26].

The photoreduction of ferredoxin and the resultant cyclic or non-cyclic photophosphorylation were found to be basically independent of photoproduction of oxygen by chloroplasts[27]. To demonstrate this independence it was necessary to use special experimental devices such as inhibitors of oxygen evolution, anaerobic conditions and, most recently, far-red monochromatic light[27]. Cyclic photophosphorylation catalysed by ferredoxin was found to occur at 708 mμ—a wave-length of light which is absorbed by the chlorophyll *a* pigment system but not by chlorophyll *b* (ref. 36) and at which photoproduction of oxygen by chloroplasts is greatly diminished[27,37]. These results are consistent with the view that photoproduction of oxygen by chloroplasts is an accessory photochemical

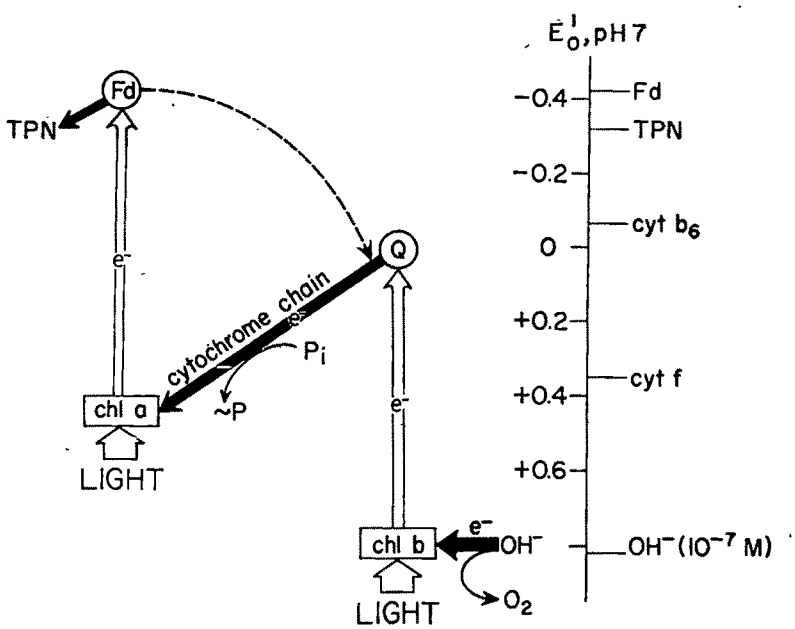

Fig 1. Scheme for two photoreactions and their relation to ferredoxin-dependent cyclic and non-cyclic photophosphorylation in chloroplasts. Details in the text

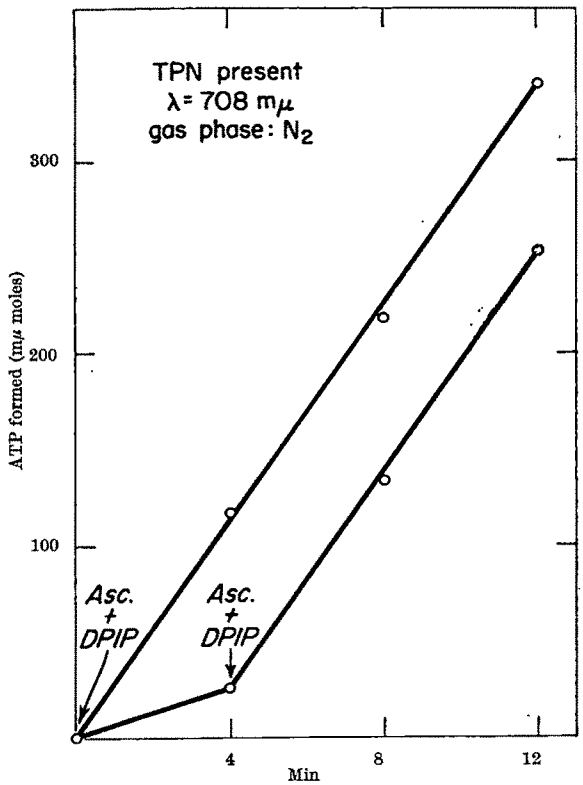

Fig. 2. Non-cyclic photophosphorylation at 708 mμ. The reaction mixture contained in a final volume of 3·0 ml., broken chloroplasts equivalent to 400 μg of chlorophyll, 500 μg of spinach ferredoxin and the following in μmoles: *tris* buffer, pH 8·3, 100; $MgCl_2$, 5; ADP, 2; $K_2HP^{32}O_4$, 2; and triphosphopyridine nucleotide (TPN), 2. Sodium ascorbate (20 μmoles) and dichlorophenol indophenol (DPIP) (0·2 μmoles) were added at the times indicated. The reaction was carried out in Warburg vessels under nitrogen at 15° C. Light intensity was 5·0 μeinsteins per min. The reaction vessels were capped with rubber serum bottle stoppers, through which, at the indicated times, 0·5 ml. aliquots of the reaction mixture were withdrawn (with a syringe) for ATP determination. The ATP formed is plotted as mμmoles ATP formed per 1·5 ml. of reaction mixture

reaction dependent mainly on chlorophyll *b*, which in chloroplasts serves as an 'accessory' pigment system, analogous to accessory pigment systems such as the phycobilins, found only in oxygen-evolving photosynthetic cells.

To recapitulate, the biochemical analysis of the photochemical activity of isolated chloroplasts has led to a distinction between two main component photochemical reactions (Fig. 1): (1) the photoproduction of oxygen, a reaction for which the accessory chlorophyll *b* pigment system is essential; (2) the photoreduction of ferredoxin (leading to triphosphopyridine nucleotide reduction and photophosphorylation), a reaction which is basically independent of chlorophyll *b* in that it can be experimentally driven by the chlorophyll *a* pigment system alone. We will present new evidence that supports this interpretation and also clarifies further the relationship between cyclic and non-cyclic photophosphorylation in chloroplasts.

Cyclic and Non-cyclic Electron Flow at 708 *mμ*. In the scheme, represented by Fig. 1 (based on Fig. 3 in ref. 4) we envisage that non-cyclic photophosphorylation by chloroplasts is coupled with an 'uphill' flow of electrons from water (OH^-) to triphosphopyridine nucleotide—an electron flow which is driven by two photochemical reactions working in series[4,38]. The first photoreaction lifts electrons from the redox potential (at *p*H 7) of water-oxygen ($E_0' = 0{\cdot}82$ V) to that of plastoquinone[39] ($E_0' \sim 0$ V) and is driven by chlorophyll *b* (henceforth referred to as photoreaction *B*). The second photoreaction lifts electrons from the level of cytochrome *f* (ref. 40) ($E_0' = 0{\cdot}365$ V) to that of ferredoxin[24] ($E_0' = -0{\cdot}43$ V) and is driven by the chlorophyll *a* pigment system (henceforth referred to as photoreaction *A*). A 'primary' phosphorylation site, common to both the cyclic and non-cyclic photophosphorylation pathways, is considered to be coupled with a 'downhill', dark electron transfer—one in accordance with the thermodynamic gradient—which joins the two photochemical reactions and probably involves a transfer of electrons from plastoquinone (*Q*) to the chloroplast cytochromes and thence to chlorophyll *a* (long black arrow in Fig. 1). In addition, the ferredoxin-catalysed cyclic photophosphorylation is envisaged as having at least one more phosphorylation site, coupled with the electron transport sector that is marked in Fig. 1 by a broken line.

It can be predicted from the scheme in Fig. 1 that at 708 mμ, non-cyclic photophosphorylation, coupled with triphosphopyridine nucleotide reduction, should occur when the ascorbate-dichlorophenol indophenol (ascorbate-DPIP) couple and not water is the electron donor system. The transfer of electrons from water to triphosphopyridine nucleotide would require the participation of both photoreactions *B* and *A*, whereas the transfer of electrons from the ascorbate-DPIP couple to triphosphopyridine nucleotide would require the participation of only photoreaction *A*.

These predictions were based on the following observations: (1) The ascorbate-DPIP couple photoreduces triphosphopyridine nucleotide in the presence of inhibitors of oxygen evolution[41]. (2) The ascorbate-DPIP couple serves as the electron donor system for a triphosphopyridine nucleotide-coupled non-cyclic photophosphorylation when the flow of electrons from water is blocked[4]. (3) The photoreduction of triphosphopyridine nucleotide by the ascorbate-DPIP couple, as contrasted with the photoreduction by water, is not affected by an extraction of plastoquinone (*Q* in Fig. 1) from chloroplasts[39,42].

Fig. 2 shows how the predictions from the scheme have been experimentally verified. At 708 mμ, a wave-length at which photoreaction *B* could not occur (because chlorophyll *b* does not absorb at this wave-length), little non-cyclic photophosphorylation took place unless ascorbate-DPIP was supplied as the electron donor system

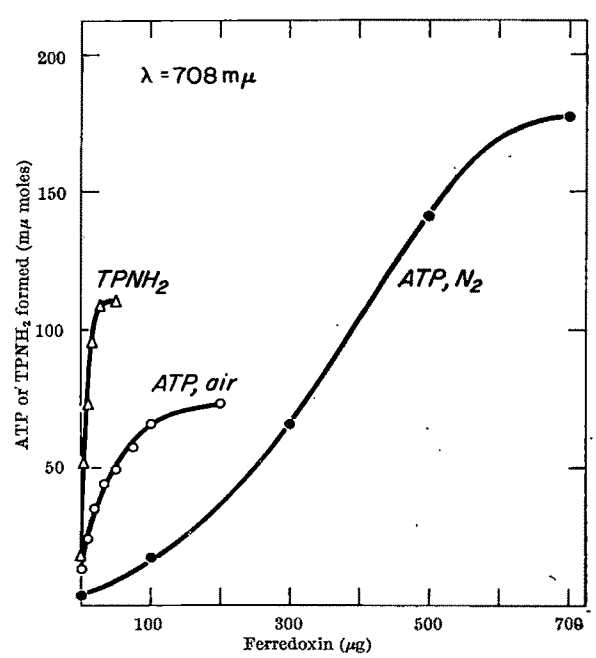

Fig. 3. Photochemical reactions of isolated chloroplasts at 708 mμ as a function of ferredoxin concentration. Left curve: photoreduction of triphosphopyridine nucleotide (TPN) by the ascorbate-DPIP couple under nitrogen (see legend for Fig. 2). Middle curve: cyclic photophosphorylation under air. Right curve: cyclic photophosphorylation under nitrogen. No co-factor of photophosphorylation other than ferredoxin was added to the reaction mixtures

for the reduction of triphosphopyridine nucleotide. The low rate of non-cyclic photophosphorylation which was observed prior to the addition of the ascorbate-DPIP couple (lower curve, Fig. 2) was probably due to chromatic impurities remaining in the 708 mμ light beam.

Fig. 3 shows cyclic photophosphorylation at 708 mμ as a function of ferredoxin concentration under aerobic and anaerobic conditions. Lower concentrations of ferredoxin were more effective under aerobic than under anaerobic conditions in catalysing cyclic photophosphorylation, but a higher maximal rate of photophosphorylation was observed under anaerobic conditions. Fig. 3 also shows that, in the presence of ascorbate-DPIP as the electron donor system, ferredoxin has a greater affinity for the reduction of triphosphopyridine nucleotide than for the cyclic electron flow pathway. The reduction of triphosphopyridine nucleotide proceeded equally well under aerobic and anaerobic conditions.

The apparent Michaelis constants have been computed from data represented by Fig. 3 in order to compare the affinity of ferredoxin for the cyclic and non-cyclic electron flow pathways in chloroplasts. The values for non-cyclic, aerobic cyclic and anaerobic cyclic photophosphorylation are, respectively: $3{\cdot}3 \times 10^{-7}$ M, $2{\cdot}3 \times 10^{-6}$ M and $1{\cdot}9 \times 10^{-5}$ M.

The high affinity of ferredoxin for the non-cyclic electron flow is in agreement with the previously observed dominance in chloroplasts of non-cyclic photophosphorylation over cyclic photophosphorylation, so long as triphosphopyridine nucleotide is available as the electron acceptor[26]. This high affinity of ferredoxin for the non-cyclic electron flow to triphosphopyridine nucleotide also explains the inhibitory effect of triphosphopyridine nucleotide on the ferredoxin-catalysed cyclic photophosphorylation at 708 mμ, which is shown in Fig. 4. These results are also consistent with the scheme in Fig. 1.

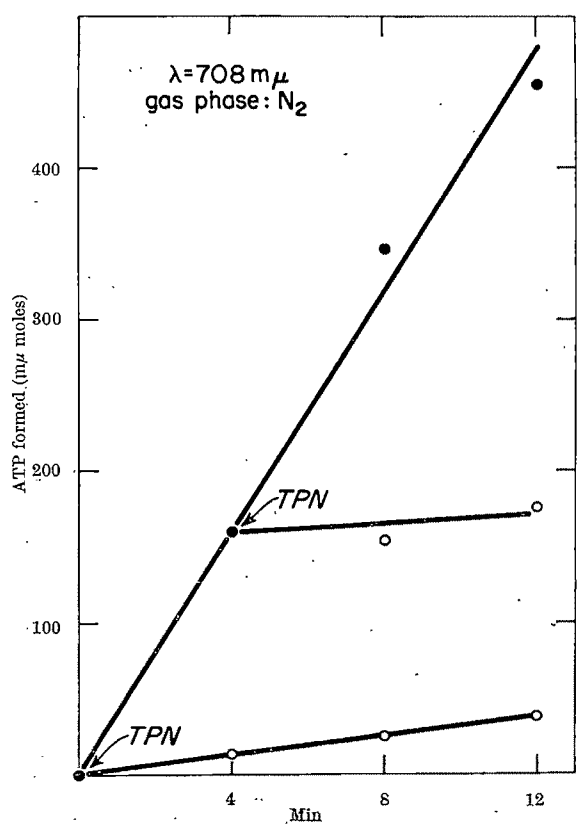

Fig. 4. Effect of triphosphopyridine nucleotide on ferredoxin-dependent cyclic photophosphorylation under anaerobic conditions at 708 mμ. The experimental conditions were as given for Fig. 2, except that ascorbate and DPIP were omitted. TPN (2·5 μmoles) was added only as indicated

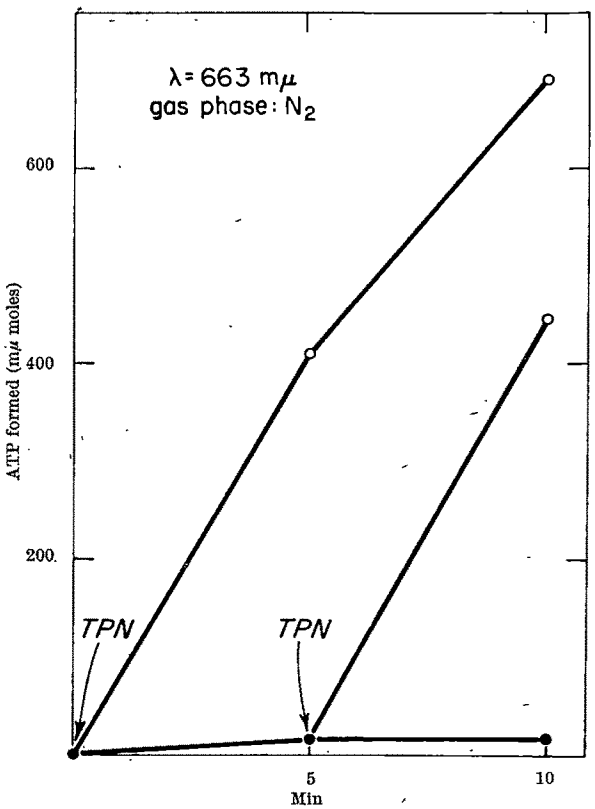

Fig. 5. Effect of triphosphopyridine nucleotide on ferredoxin-dependent cyclic photophosphorylation under anaerobic conditions at 663 mμ. Experimental conditions were as given for Fig. 4, except that the reaction mixtures were pre-illuminated for 5 min at 663 mμ, under nitrogen. Light intensity was 6·0 μeinsteins per min throughout

At 708 mμ photoreaction *B* is inoperative; therefore, water cannot serve as the electron donor and the added triphosphopyridine nucleotide now acts as a 'trap' which drains off electrons (via ferredoxin) and thus prevents their cyclic flow. Without an alternative electron donor system (ascorbate-DPIP couple) that would be effective at 708 mμ (cf. Fig. 2), ferredoxin would remain in the oxidized state and, as a result, all photophosphorylation, cyclic and non-cyclic, would of necessity cease. It is noteworthy that although reduced ferredoxin is auto-oxidizable, molecular oxygen did not, like triphosphopyridine nucleotide, act as an electron trap to prevent the cyclic electron flow.

Photophosphorylation at 663 mμ. Fig. 5 shows that at 663 mμ, under anaerobic conditions, cyclic photophosphorylation did not occur (bottom curve). However, the addition of triphosphopyridine nucleotide readily established non-cyclic photophosphorylation (middle and upper curves). At 663 mμ both photoreactions *A* and *B* were possible and hence, in accordance with the scheme in Fig. 1, the transfer of electrons from water to triphosphopyridine nucleotide and the accompanying phosphorylation would be assured.

The inability of monochromatic light at 663 mμ to support cyclic photophosphorylation under anaerobic conditions (bottom curve in Fig. 5) was observed after pre-illuminating the chloroplast system at this wave-length

Table 1. Effect of Pre-illumination at 663 mμ and Aeration on Ferredoxin-dependent Cyclic Photophosphorylation at 708 mμ

Treatment	mμmoles ATP formed/4 min
1. Control	127
2. 5 min pre-illumination in N_2	16
3. 5 min pre-illumination in air	105
4. Treatment 2 followed by 5 min aeration in the dark	126

The reaction mixture was as given for Fig. 4. The light intensity was 2·5 and 4·9 μeinsteins per min at 663 mμ and 708 mμ, respectively. Pre-illumination at 663 mμ was for 5 min. The reaction time was 4 min.

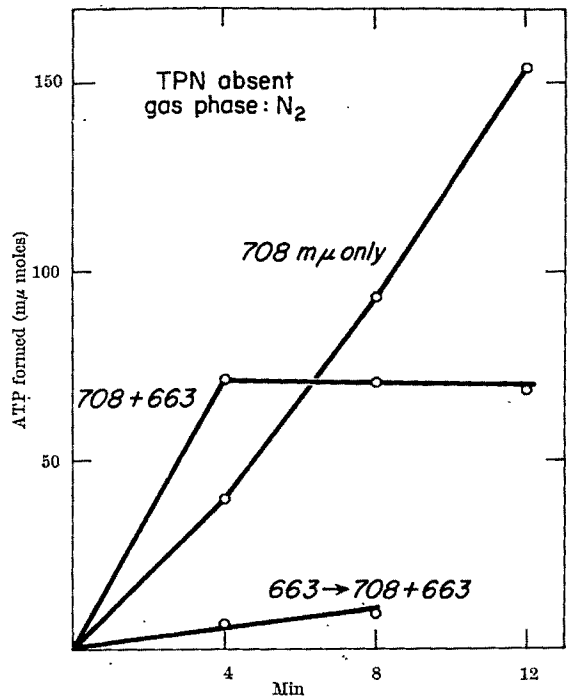

Fig. 6. Effect of additional illumination at 663 mμ on ferredoxin-dependent cyclic photophosphorylation at 708 mμ, under anaerobic conditions. Bottom curve: 4 min pre-illumination at 663 mμ under nitrogen, followed by joint illumination with the two monochromatic beams (663 mμ and 708 mμ). Middle curve: illumination was by the 708 mμ band only without pre-illumination. Left curve: joint illumination with the two beams (663 mμ and 708 mμ) without pre-illumination. Reaction mixture was as given for Fig. 4. Light intensity was 2·6 and 3·1 μeinsteins per min at 663 mμ and 708 mμ, respectively

for 5 min, under nitrogen. It was essential to maintain anaerobic conditions during the pre-illumination period to observe the subsequent suppression of anaerobic cyclic photophosphorylation at 663 mμ. Cyclic photophosphorylation was not suppressed when the pre-illumination was carried out in air or when anaerobic pre-illumination was followed by 5 min of aeration in the dark, prior to exposure to the actinic light beam at 663 mμ (Table 1).

The results shown in Fig. 5 and Table 1 are explained by the following hypothesis. As already stated, non-cyclic electron flow in chloroplasts is a unidirectional electron transfer from water to triphosphopyridine nucleotide and is driven by photoreactions *B* and *A*. This unidirectional electron flow keeps the intermediates in the electron transport chain in a partly reduced state. The problem of 'over-reduction' does not arise so long as the electron acceptor, triphosphopyridine nucleotide (or ultimately carbon dioxide) is available. A different situation, however, arises in the case of cyclic photophosphorylation. To maintain a cyclic electron flow from reduced ferredoxin back to the electron transport chain, the intermediates in the chain must be at least partly oxidized. If they are kept in a reduced form they cannot accept electrons from reduced ferredoxin.

Our hypothesis proposes that molecular oxygen normally regulates the redox balance for the electron transport chain involved in cyclic photophosphorylation by chloroplasts. In the presence of oxygen, the electron transport system of chloroplasts does not become over-reduced by the flow of electrons from water. But under anaerobic conditions, the flow of electrons from photoreaction *B* over-reduces the components of the electron transport chain in chloroplasts and this over-reduction cannot be counterbalanced by the regulatory oxidizing action of oxygen.

In accordance with previous interpretations[13,5], the present hypothesis excludes a proposed electron acceptor role for oxygen in cyclic photophosphorylation (chloroplasts do not contain cytochrome oxidase and do not respire[43,44]), but envisages for oxygen an important role as a redox regulator for cyclic photophosphorylation. This hypothesis explains why in white light, or in shorter wave-lengths of monochromatic light which permit photoreaction *B* to occur, aerobic conditions are necessary for the ferredoxin-dependent cyclic photophosphorylation. Oxygen is needed to prevent photoreaction *B* from over-reducing the system, thereby bringing cyclic photophosphorylation to a halt. Under these conditions of illumination, ferredoxin-dependent cyclic photophosphorylation can be made to proceed without oxygen only if photoreaction *B* is blocked by the use of specific inhibitors, for example, *p*-chlorophenyldimethyl urea[26]. Alternatively, cyclic photophosphorylation can be made to proceed under anaerobic conditions by using far-red monochromatic light which excludes photoreaction *B* (ref. 27 and Fig. 2).

Photophosphorylation with Two Beams of Light. The hypothesis just presented is also supported by experiments with two beams of light, as illustrated in Figs. 6 and 7. Fig. 6 shows that, under anaerobic conditions, cyclic photophosphorylation at 708 mμ is inhibited by the addition of a second monochromatic beam of light at 663 mμ. This chromatic inhibition, which we attribute to over-reduction by the 663 mμ beam, occurred immediately when illumination by the combined 708 and 663 mμ beams was preceded by pre-illumination at 663 mμ (bottom curve, Fig. 6). Without a pre-illumination treatment, the inhibitory effect of the 663 mμ beam, added to the 708 mμ beam, was observed only after 4 min. Evidently an interval of time was needed to bring about a sufficient state of over-reduction by the 663 mμ beam.

Unlike cyclic photophosphorylation, non-cyclic photophosphorylation with triphosphopyridine nucleotide was favoured by the combination of the two beams of monochromatic light (Fig. 7). No phosphorylation coupled with photoreduction of triphosphopyridine nucleotide by water occurred at 708 mμ alone (bottom curve, Fig. 7). Supplementary illumination at 663 mμ,

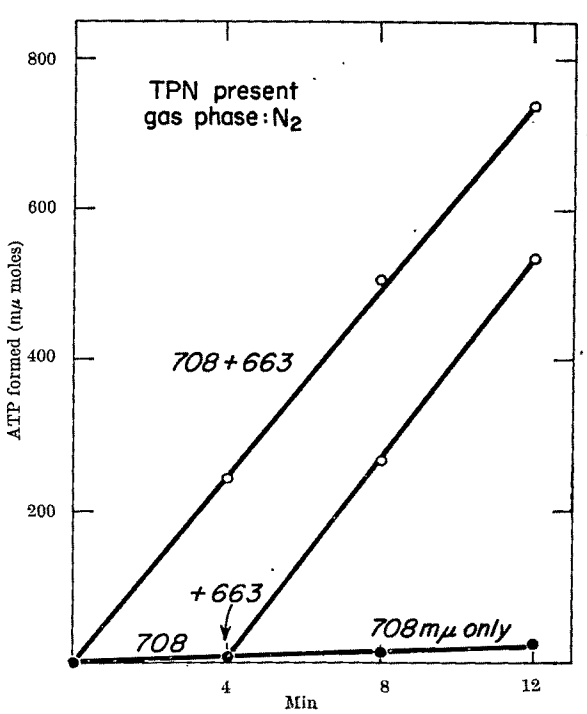

Fig. 7. Effect of additional illumination at 663 mμ on non-cyclic photophosphorylation at 708 mμ, under anaerobic conditions. Illumination at 708 mμ was given in all cases, but additional illumination at 663 mμ was supplied at the start of the experiment (top curve) or after 4 min (middle curve). No pre-illumination was given. Light intensity was as given for Fig. 6. Reaction mixture was as given for Fig. 4 except that 2·5 μmoles TPN was added in all cases

when given at the start, made photoreaction *B* and the resultant non-cyclic photophosphorylation possible from the beginning of the illumination period (Fig. 7). Alternatively, the non-cyclic photophosphorylation could be delayed by delaying the addition of the 663 mμ beam (middle curve in Fig. 7).

Concluding remarks. The findings reported here support the idea that in illuminated chloroplasts the conversion of radiant energy into chemical energy is accomplished by two main photoreactions: photoproduction of oxygen, dependent on light absorbed by the chlorophyll *b* pigment system, and photoreduction of ferredoxin, dependent on light absorbed by the chlorophyll *a* pigment system. The experiments with monochromatic light reported here were not designed to give any information about the association of other pigments, such as carotenoids or variants of chlorophyll *a* (ref. 1), with the two main pigment systems in chloroplasts. This question must be left for future experimentation.

Our results indicate that at selected far-red wavelengths of light, which are not absorbed by chlorophyll *b* and give no oxygen evolution, the chlorophyll *a* pigment system can drive the photoreduction of ferredoxin and the ensuing cyclic and non-cyclic photophosphorylation (the latter only when a suitable electron donor is supplied). The photoactivity of chlorophyll *a* cannot replace the photoactivity of chlorophyll *b*.

The two photochemical reactions shown in Fig. 1 are envisaged as being joined by a 'thermochemical bridge', connecting reduced plastoquinone with cytochrome. Such an interpretation is consistent with the observations of Myers and French[45] on whole cells, which argue against a physical transfer of energy from one photosynthetic pigment to another. In their experiments, enhancement of quantum yields by two beams of light could be seen when the two beams were not supplied simultaneously but were alternated in periods of several seconds—an interval of time too long for a direct energy transfer mechanism. However, we consider it still premature to go beyond tentative formulations on the possible energy transfer mechanisms in chloroplasts.

The idea of redox balance as a condition for cyclic photophosphorylation in chloroplasts has its counterpart in photosynthetic bacteria[18,19,46]. However, since photosynthesis in bacteria, unlike chloroplasts, produces no oxygen, oxygen cannot be invoked as a redox regulator for bacterial cyclic photophosphorylation under physiological conditions. In chloroplasts, according to our hypothesis, oxygen fulfils an important physiological function as a redox regulator in cyclic photophosphorylation. Thus, chloroplasts which lack the enzymatic equipment to use oxygen for respiration are considered to be dependent on oxygen for regulation of photochemical activity.

The methods used in this investigation are described elsewhere[27]. One of us (D. I. A.) thanks Prof. Otto Warburg for the hospitality of his Institute where, as a guest investigator in 1955–56, he learned the optical and photometric techniques used in this investigation. We thank Prof. J. E. Gullberg for advice and Lars O. Björn for assistance in the initial assembly and testing of the optical apparatus. Richard K. Chain, Berah D. McSwain and William Ufert have given excellent technical assistance with the present experiments. This work was supported by grants from the U.S. National Institutes of Health and the Office of Naval Research.

FLAVOUR OF BEEF AND WHALE MEAT

By IRWIN HORNSTEIN, PATRICK F. CROWE and WILLIAM L. SULZBACHER

Meat Laboratory, Eastern Utilization Research and Development Division,
United States Department of Agriculture, Beltsville, Maryland

As a result of a series of investigations of beef, pork and lamb[1–3], we concluded that an identical basic meaty aroma is associated with the lean portion of these red meats and that species flavour differences reside in the fat. To check the validity of the conclusion, that lean meats contribute an identical meaty aroma, we have now compared the volatiles, both chemically and organoleptically, of lean whale and lean beef. If differences in

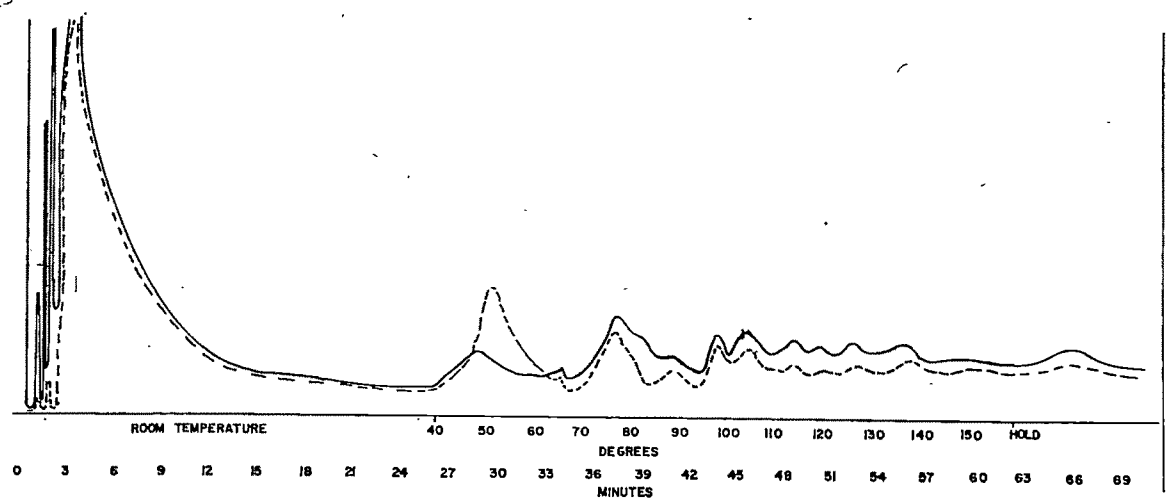

Fig. 1. Comparison of the chromatographic patterns obtained from lean beef and lean whale volatiles. The third peak on whale pattern is absent in beef and represents trimethylamine. Thick line, whale volatiles; dashed line, beef volatiles

the basic meaty flavour derived from lean meats of different species of animals do exist, one might expect to find them in a mammal that lives in an environment and subsists on a diet so completely alien to that of its terrestrial relatives.

Approximately 20 lb. of lean whale meat were obtained from a 49-ft. sei whale, *Balaenoptera borealis*[4], less than 20 h after it was killed. The sample was frozen, packed in dry ice and flown to the laboratory where it was kept at dry-ice temperature until needed.

For flavour evaluations, steaks 1 in. thick were cut from the sample, heated to an internal temperature of 150° F and tasted by the laboratory personnel. The results were uniformly unfavourable; all tasters said the steaks were 'fishy', and descriptive terms such as 'metallic', 'oily', and 'rancid' were also used by the panel. The procedures used to concentrate the flavour precursors in lean meats[1–3] were applied to the lean whale meat. The following operations were carried out at 0°–4° C. Whale meat (1 kg) was ground and homogenized with 1,500 ml. of water. The slurry was centrifuged, filtered and the extract lyophilized to yield 50 g (5 per cent of starting weight) of a water-soluble red-brown powder. 100 ml. of a 5 per cent solution of the powder (*p*H 5·2) were refluxed. This solution gave a strong 'fishy' aroma that soon disappeared and was replaced by a typical meaty aroma indistinguishable from the cooked meat aroma obtained from similar solutions prepared from beef, pork or lamb powders. The whale 'broth' by odour evaluation was rated excellent and described as 'meaty' but without any species identity being attached to the 'meaty' aroma.

Chemical comparisons of lean beef and whale volatiles were made on freeze-dried extracts of the lean meats; 30 g of powder were vacuum pyrolysed at 100° C and 10^{-5} mm mercury. Total volatiles were condensed in a trap surrounded by liquid nitrogen. The total volatiles were in turn fractionated at 10^{-6} mm mercury by allowing the trap containing the total volatiles to come to room temperature and collecting fractions at liquid nitrogen temperature and at dry ice–acetone temperature. A small amount of residue remained in the total condensate trap. The techniques and apparatus were previously described[1,2]. The aroma of the fractions from whale were identical to their counterpart fractions from beef. Of particular interest was the residue in the total condensate trap, which in both whale and beef consisted of a very small amount of a colourless, viscous, water-soluble liquid of a pleasant, fruity odour that, on exposure to air, slowly darkened and assumed a 'meaty' aroma. The volatiles were analysed for acidic and basic compounds by conversion to their salts and their subsequent analyses[1]; for carbonyl compounds, by conversion to 2,4-dinitrophenylhydrazones[1], and by separation of these derivatives on paper[5,6]; for hydrogen sulphide, by conversion to methylene blue by a modified procedure of Marbach and Doty[7]; and for lactic acid, by the colorimetric method of Hullin and Noble[8].

Compounds positively identified in the volatiles from whale, other than water and carbon dioxide, included ammonia, methylamine and trimethylamine, hydrogen sulphide and methyl mercaptan, formaldehyde, acetone and acetaldehyde, and lactic acid and its ammonium salt. Of these compounds, only trimethylamine was absent in the beef volatiles.

In a separate set of experiments, 5 g of whale powder were heated for 45 min at 100° C with nitrogen flowing over the sample, at a rate of approximately 30 ml./min. The volatiles were trapped on a collection coil[9] and separated by gas chromatography. The column was an 8 ft. × ⅛ in. outer diameter, stainless steel coil; the liquid phase was 20 per cent castorwax on acid-washed 'Chromosorb-*P*'. The column was temperature programmed, and a flame ionization detector was used[10]. 5 g of beef powder were treated in identical fashion. The gas chromatographic patterns are shown in Fig. 1. The qualitative agreement between the two traces is excellent. Only one peak is not common to both, and that is the trimethylamine peak present in whale. The gas stream was split after emergence from the column, part going to the flame detector and the rest to the nostrils of an observer. The path-lengths, after emergence from the column, were so adjusted that the odour could be noted as the peak was being recorded. No one compound could be assigned the designation of 'meaty'; however, the collective fractions above 70° C were much more characteristic of meat than were the collective fractions below 70° C. These chromatograms were obtained at high sensitivity, and the peaks at the higher temperatures correspond to microgram amounts of material.

Studies of whale depot fat have shown this to be highly unsaturated[11–13]. If the intramuscular lipid fraction was similarly unsaturated, oxidation could account for the observed off-flavour of the whale steaks. The fatty composition of the lipid fractions extractable from lean whale and lean beef were therefore compared. 100 g of diced meat were extracted according to the procedure of Folch *et al.*[14] with 2 : 1 chloroform–methanol. The lipid fraction, after clean-up and solvent removal, was dissolved in a minimum of 20 : 1 chloroform–methanol and chromatographed on silicic acid. Chloroform containing increasing amounts of methanol was used to successively elute two triglyceride fractions, a cephalin fraction,

and a mixed lecithin–sphingomyelin fraction[15]. The fatty acid composition of the combined triglyceride fraction and each of the other fractions was determined by hydrolysis of an appropriate aliquot, followed by conversion of the fatty acids to their methyl esters and their subsequent separation by gas chromatography[15,16].

Retention volume data were obtained on both a non-polar 'Apiezon' substrate and on a polar diethyleneglycol succinate ('DEGS') substrate. Packed columns, 20 per cent substrate on acid-washed 'Chromosorb *P*', 7 ft. × ⅛ in. outer diameter stainless steel, were used. Columns were operated isothermally at 202° C with the 'Apiezon' column and at 192° C with the 'DEGS' column[10]. Identification of the acids was in the main based on both a comparison of the retention volumes of the methyl esters with knowns and on plots of log of retention volume versus chain length for both liquid phases[16]. In Table 1, the fatty acid composition is given for the combined triglyceride fractions, the cephalin fraction, and the combined lecithin–sphingomyelin fraction in whale and beef. The profound difference in the fatty acid composition of the triglyceride fractions is particularly striking. Beef triglycerides contain no fatty acids above C_{18}; whale triglycerides contain approximately 37 per cent C_{20} and C_{22} fatty a... and about 75 per cent of these contain four or more doub... bonds. The differences in terms of unsaturation in the fatty acid composition of whale and beef liquids are summarized in Table 2.

In a comparison of the phospholipids in lean pork and beef, we noted that the isolated, highly unsaturated, phospholipid fractions quickly assumed fishy, unpleasant off-flavours, while in the total lipid extract, which contained large amounts of the relatively saturated triglycerides, this development of off-flavour was retarded[15]. The whale triglyceride fraction, on the other hand, is actually more unsaturated than the phospholipid fraction and, rather than retarding the development of oxidative off-flavours, probably enhances their development. This high degree of unsaturation of the lipid fraction triglycerides, in combination with the trimethylamine presumably formed by the reduction of the trimethylamine oxide present in the whale's food supply, could well account for the poor flavour of the whale meat. The organoleptic and chemical evaluation of the water-extractable portion of the lean whale meat confirms the supposition that a basic meat flavour originates in the lean portions of meats. A corollary can be added; the lean meat, which is in essence an aqueous phase, can act as a reservoir for extraneous, water-soluble materials, in this case, for trimethylamine oxide, that may also affect flavour.

MICROBIOLOGY OF ANTARCTIC SEA-ICE

Microalgae and Antarctic Sea-ice

THOSE who have travelled through far southern antarctic waters will be familiar with the brown coloration commonly visible as bands in sea-ice, especially in the lowermost layers. This colour is caused by diatoms growing on or trapped within the ice. In spite of their widespread occurrence and prolific growth, they do not appear to have attracted closer study in their normal habitat, although a good deal of material from these populations has, without doubt, been recovered in phytoplankton hauls, for example, Heiden and Kolbe[1], Hart[2].

One reason for our lack of knowledge of this flora centres round the fact that most investigations in the past have been carried out from ships rather than from fixed stations associated with bases on the antarctic mainland. Even working through holes in the ice, it is clear that very little or no information concerning the attached flora would be obtained unless special techniques were adopted.

One of us[3] first became interested in these organisms at the Australian Antarctic Station, Mawson, during 1956, when they were found well developed on the undersurface of sea-ice some 1·4 m thick at a time when the amount of light penetrating to their habitat must have been very limited. More recently, during the 1961–62 summer season at McMurdo Sound, diatoms were found in large quantities associated with sea-ice 2–3 m thick. At that time, it was not possible to undertake a study in any detail[4]. However, the opportunity was taken during the 1962–63 austral summer to collect a series of samples in this area to determine the species present. It is the purpose of this communication to direct attention to the main findings.

The flora was sampled on seven occasions between December 18, 1962, and January 7, 1963, at an ice-hole station over 25 m of water near Cape Armitage on Ross

Island. Aqualung equipment was used to obtain the material directly from the lower layers of the ice. During this period, the water below the ice was almost devoid of phytoplankton.

A total of 32 species of microalgae, all diatoms, were recovered from the samples. Numerical dominance was shared by 11 species, all of which were present in at least 6 of the 7 samples. These organisms were *Amphiprora kjellmanii, A. oestrupii, Biddulphia weissflogii, Coscinodiscus subtilis, Eucampia balaustium, Fragilaria linearis, Nitzschia martiana, N. seriata, Pleurosigma antarcticum, Rhizosolenia alata* and *R. rostrata*. It should be noted that, of the 11 species, 6 have been recorded previously by Heiden and Kolbe[1] among pack ice or close to the mainland of Antarctica, and 5 included by Hart[2] in his group of typically neritic and ice-edge forms.

Here, it should be mentioned that we are not satisfied with the terminology which has been applied to these organisms, for example, by Hart. A clear distinction should be drawn between species especially adapted for life in the sea-ice habitat and those which are permanently planktonic. There are, in effect, two plant communities; the epontic community and the planktonic community. The epontic community in this enviroment consists, as it does in the estuaries of lower latitudes, of attached species of *Pleurosigma, Nitzschia, Amphiprora, Fragilaria*, etc., as well as of non-attached species living with them as part of that community, that is, species of *Biddulphia, Coscinodiscus, Asteromphalus*, etc.

With the deterioration of the sea-ice during the summer, the identity of this community is inevitably lost. Although the members of the epontic community must, at these times, be recovered with the plankton, it should be remembered that their development has taken place under conditions which, in several respects, are dissimilar to those to which the typical plankton is exposed. The application of the term 'meroplankton' to such organisms seems to us misleading and inappropriate in that it gives no indication of their origin. To describe the members of this community as 'ice-edge' forms is clearly not acceptable.

There are several reasons which make the recognition of separate epontic and planktonic communities important. Apart from the intrinsic biological interest of microalgae in the sea-ice habitat, it is clear that, in the presence of an ice-associated flora, assessment of the primary productivity of this region cannot be based solely on measurements of photosynthetic activity in the water column below the ice. Further, it seems probable that the development of the epontic community, by further reducing levels of submarine illumination, may exert a significant limiting influence on the activities of phytoplankton present beneath the sea-ice. In this connexion, it is noted that a sudden increase in under-ice illumination, particularly during the 1961–62 summer, appeared to be related, at least in part, to the loss of the epontic community coincident with deterioration in the lower layers of the sea-ice.

While present results (see following communication) indicate that at least low levels of illumination are necessary for the growth of diatoms associated with sea-ice, it is by no means certain that heterotrophic growth does not occur. Here, it may be relevant to note that potentially photosynthetic micro-organisms have been recorded at depths from 500 to 4,000 m in the open sea by Bernard[5], by a group at Miami and by Wood (unpublished). These workers have found chlorophyll-containing coccolithophores, dinoflagellates (*Exuvialla* and *Gymnodinium*), blue-green algae (*Nostoc* and *Oscillatoria*) and chrysomonads (*Isochrysis* spp.) at such depths, in some cases in samples taken under aseptic conditions, and have cultivated them or shown the presence of chlorophyll by fluorescence. Oppenheimer and Wood[6] found chlorophyll-containing organisms in sediments to a depth of 11 cm, and Claus[7] has found up to 90 species of chlorophyllous algae in caves recently opened in Hungary. Kriss and Rukina[8] found photosynthetic sulphur bacteria at 2,500 m in the Black Sea. The presence of potentially photosynthetic organisms as apparently normal inhabitants of regions of subliminal or zero illumination seems worth comment, especially as they occur in such widely different habitats.

The field work was carried out during the tenure of grant No. G18021 from the U.S. National Science Foundation.

Diatoms of Antarctic Sea-ice as Agents of Primary Production

In the preceding communication, Bunt and Wood have given a brief description of the epontic community of diatoms associated with the lower layers of the sea-ice in McMurdo Sound. I should like, now, to describe the ice habitat and to present information relating to the concentrations of organisms, which this habitat supports and to their activities as agents of primary production.

There were several problems of a practical nature peculiar to this investigation. During the 1961–62 austral summer, the possibility of obtaining estimates of the concentrations of organisms in the ice flora by taking samples from ice upturned in the path of ice-breakers was abandoned when it was observed that an appreciable proportion of the population was dislodged into the water below the ice and could not be recovered quantitatively. Further, the material remaining attached to the ice rapidly became frozen on exposure to the air so that it was unsuitable for laboratory measurements of photosynthetic activity. It became apparent that sampling would have to be undertaken directly from the lower layers of undisturbed sea-ice and that such a procedure would require diving equipment. Very little diving has been undertaken in polar waters, particularly in areas entirely covered by sea-ice. Nevertheless, having had brief experience with such activities in ice-free water at Mawson in 1956 and having received some advice from Peckham (personal communication) for conditions in McMurdo Sound, it was decided that such an approach might be practicable. The equipment used was similar to that described by Fane[1].

Access to the water was obtained through holes in the sea-ice maintained under the floor of small field laboratories (62*B* and 62*E*), similar to but less elaborate than that described by Tressler[2]. The depth of water at the former station was 300 m, and at the latter 25 m. Both stations were off Cape Armitage on Ross Island. During the study the ice was 4–5 m thick, with an additional snow cover of variable thickness. The results in this article refer almost exclusively to 62*E*.

The appearance of blocks of sea-ice, upturned in the passage of ships, gives a most misleading picture of the habitat occupied by the ice flora. *In situ* inspection of the undisturbed ice shows that it consists of two distinct zones, a relatively thick upper layer which is dense and hard, and a lower layer, 0·5–1 m thick, which is easily disrupted and washed away when the integrity of the ice is disturbed. It is this layer which supports algal growth. Unlike the main mass of sea-ice, it consists of a relatively loosely aggregated matrix of large, plate-like ice crystals and a considerable proportion of unfrozen water. Although

the boundary between the matrix of crystals and the main water column is sharply defined and generally plane, there are many local irregularities. The lower surface is not smooth, but composed of more or less uniformly projecting ice crystals.

In such a system it is difficult to determine the precise disposition of the algal community. However, present field and laboratory observations indicate that many species in the flora grow attached to the surfaces of individual ice crystals, while others derive physical support from sessile forms or exist in more or less free suspension in the interstices within the ice matrix. Certainly, it is clear that the organisms are distributed throughout the loosely aggregated layer and are even present in large numbers in the lower few centimetres of the upper dense layer of sea-ice. In fact, it is this thin stratum that can be seen when sea-ice is broken and turned over by ships.

With the nature of the habitat unknown until the first dive was undertaken, and in the face of various practical difficulties, it was not feasible to design appropriate sampling equipment for use in the present study. Instead, it was decided to collect samples by the simple expedient of dislodging, manually, large quantities of ice crystals from beneath the sea-ice in the vicinity of the lower rim of the hole, recovering this material after allowing it to float to the surface. In spite of the obvious deficiencies of this procedure, it is felt that the results obtained at this early stage are of sufficient interest to justify their presentation.

Samples of ice crystals from Station 62*E* were collected at intervals during December 12, 1962–January 4, 1963. As a standard practice, samples were placed in clean plastic buckets and held at −1·5° C. Under these conditions, the ice did not alter state, while interstitial water soon gravitated to the bottom of the bucket. Samples of ice and seepage water were retained separately for the determination of chlorinity and *p*H.

The results of these determinations, together with parallel values for the water immediately below the sea-ice, are shown in Table 1. It has been assumed, for the present, that the water drained from collected ice crystals is representative of the interstitial water of the ice layer *in situ*. Whether or not this is entirely true remains to be verified. However, it may be seen that both the *p*H and chlorinity of this water is lower than that of the water immediately below the sea-ice and that the ice crystals, when melted, give *p*H and chlorinity values considerably lower than both the seepage water and the water below the ice. Thus, it seems likely that, between the surfaces of individual ice crystals and the interstitial water, there may exist appreciable gradients in physico-chemical conditions and in concentrations of various nutrient substances which, in turn, could exert a marked influence on the activities and distribution of the various components of the algal population. Further, the maintenance of equilibrium in the environment must lie in delicate balance, easily upset by quite small variations in temperature.

Table 1. *p*H AND CHLORINITY DATA FOR THE LOWER LAYER OF SEA-ICE AND THE WATER IMMEDIATELY BELOW THE ICE

	14.12.62		24.12.62		30.12.62		4.1.63	
	*p*H	Chlor.	*p*H	Chlor.	*p*H	Chlor.	*p*H	Chlor.
Melted ice	—	6·50	7·20	7·65	7·30	3·30	7·15	3·27
Seepage water	7·60	18·00	7·60	18·00	7·60	18·03	7·70	17·88
5 m water	7·65	19·33	7·70	19·34	7·80	19·32	7·85	19·29

Where sea-ice is re-formed annually, the ice habitat and its flora are, of course, ephemeral. In McMurdo Sound its disruption occurs some weeks in advance of the main break-out, and appears to be associated with sudden, active water movements and slight increases in temperature from around −1·7° C to approximately −1·4° C in the upper strata of the water column. In 1963, this process began about January 7 and was complete by January 13, when all traces of the laver of loose ice crystals and of the epontic community had been swept away.

Although it would have been desirable to collect data earlier in the season, the observations made during December 1962 and early in January 1963 provide a reasonably clear picture of the development of the ice flora, especially towards its peak phase. However, it should be emphasized that the concentrations of algal material reported here do not represent fully the magnitude of the flora. To obtain estimates of productivity, it was considered important to avoid the dilution of water samples with liquid derived from ice crystals. Consequently, cells firmly attached to ice surfaces were excluded from the aliquots of seepage water which were used in productivity studies as well as for pigment determinations and cell counts.

Rates of photosynthetic carbon fixation were measured with a carbon-14 technique described by Jitts[3], the incubation temperature in these studies being −1·5° C. The method of pigment analyses has been given by Humphrey[4]. Cell numbers were obtained by first passing water samples through a high-speed continuous centrifuge and counting aliquots in a Petroff–Hauser counter by fluorescence microscopy.

From Fig. 1, it may be seen that the numbers of chlorophyll-bearing cells, all diatoms, recovered in seepage water increased sharply from 4·5 × 10^6/l. on December 15, 1962, to 16·8 × 10^6/l. when the last samples were gathered on January 4, 1963. The numbers of diatoms in water samples recovered from immediately beneath the sea-ice during the same period were, by comparison, negligible. The remarkable amounts of chlorophyll *a* and *c* from the diatoms in the seepage water showed a pattern of increase very similar to the increase in cell numbers. The final concentration of chlorophyll *a* recorded was 156 mg/m³, and of chlorophyll *c*, 183 milli-specific-plankton units (MSPU)/m³. Although small values were obtained for chlorophyll *b* in several samples, these results should be treated with caution in view of the fact that this pigment is not known to occur in diatoms. Similarly, because of the doubtful reliability of the values for non-astacin

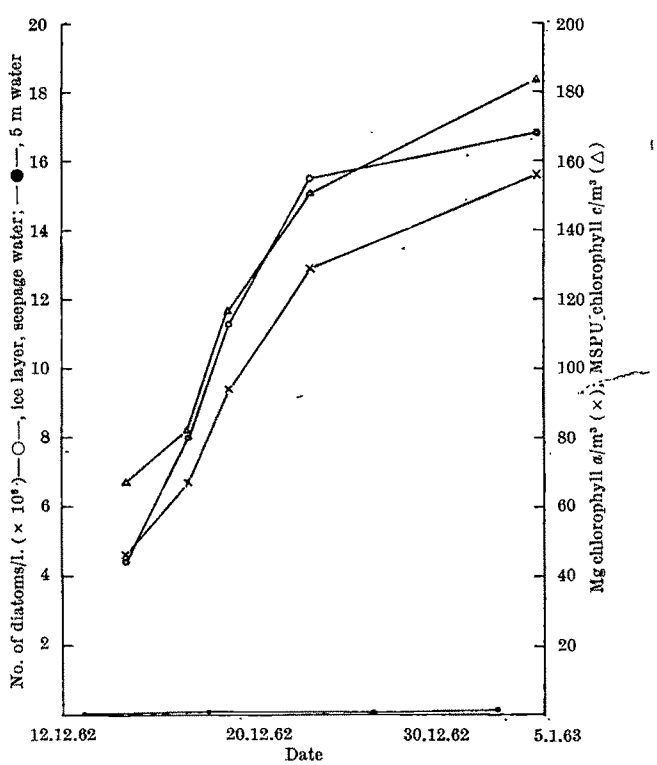

Fig. 1. Numbers of diatoms and concentrations of chlorophylls *a* and *c* in seepage water from the ice habitat at Station 62*E*. Numbers of diatoms in water below the sea-ice for comparison

[redacted]ids, the figures for this group of pigments have been presented.

At the time the peak pigment values were recorded in the seepage water, 617 mg chlorophyll a/m^3 and 543 MSPU chlorophyll c/m^3 were recovered from samples of melted ice crystals. Unfortunately, the ratio of ice crystals to interstitial water in the ice habitat was not then known. Several days later, however, some success was experienced with a hand-held van Dorn sampler during a dive at the Station 62*B*, when it was found that some 20 per cent by volume of the lower ice layer consisted of ice crystals. If this figure be taken as representative, then it may be calculated that, on January 4, 1963, there would have been approximately 248 mg chlorophyll *a* and 254 MSPU chlorophyll c/m^3 of ice layer. Although the photosynthetic activity of the organisms in the melted ice crystals was measured, the results have little meaning because the characteristics of the suspending fluid were so dissimilar to those of the interstitial water to which the cells normally would be exposed. Consequently, it is not at present known whether this component of the flora possesses an activity comparable with that displayed by the organisms in the seepage.

Since this flora was completely dispersed with the loss of the lower layers of the sea-ice soon after these observations were made, it may be assumed that these figures reflect, reasonably well, the total net production within this habitat for the 1962–63 summer season.

In the absence of data indicating the ratio between chlorophyll *a* and organic carbon in these populations, it would be unwise to apply an arbitrary factor for the expression of levels of plant growth in terms of carbon. None the less, it is clear that the production achieved under these extreme conditions is remarkably high and may well lie not far short of the maximum possible value suggested by Steemann Nielsen[5] for planktonic algae.

While the possible existence of heterotrophy cannot be excluded, there seems little doubt that the growth of the diatoms in the ice habitat results almost if not entirely from photosynthesis. In support of this contention is the observation that, at station 62*B*, where the light intensity at the depth of the lower ice layer was too low to be measured with a photocell capable of response at about 0·2 ft.-candles, very few diatoms were found. At Station 62*E*, however, present measurements indicate that the mean light intensity in the sampling zone was around 8 ft.-candles. Experiments to be described elsewhere have shown that, at this level of illumination, the diatoms of the ice flora are capable of roughly 20 per cent of the net photosynthetic activity realized at full light saturation and, therefore, possess extreme 'shade' characteristics. Further, observed rates of photosynthetic carbon fixation under conditions of weak illumination would give a pattern of increase in plant carbon very similar to that recorded for the chlorophyll pigments.

The fact that various species of diatoms are capable of reaching dense concentrations under such marked environmental limitations is not only of intrinsic interest but should also have particular relevance in the field of antarctic ecology. In this connexion, since McMurdo Sound lies so far to the south, it seems probable that the conditions there are rather more severe than those obtaining in similar situations farther to the north. Other things being equal, there seems no reason, therefore, why production, at least equivalent to that in McMurdo Sound, should not be found to occur wherever sea-ice persists into the summer season. With the information available, it is difficult to estimate the extent of sea-ice in antarctic waters at any time, although the data collated by Mackintosh and Herdman[6] suggest that perhaps 1–2 million square miles persist into mid-summer. On this basis, and assuming an average thickness for the ice habitat of 0·5 m, the production of the ice flora, in terms of chlorophyll *a*, could be of the order of $0{\cdot}3–0{\cdot}6 \times 10^6$ tons/year.

It is hoped that the findings of this investigation will lead to more extensive surveys using specially developed techniques so that the importance of primary production in the sea-ice habitat may be investigated with the thoroughness it would appear to deserve.

I thank Mr. R. Laird of Stanford University for his assistance with the diving programme. This work was made possible through support from Prof. D. E. Wohlschlag under grant No. *G*–18021 from the U.S. National Science Foundation.

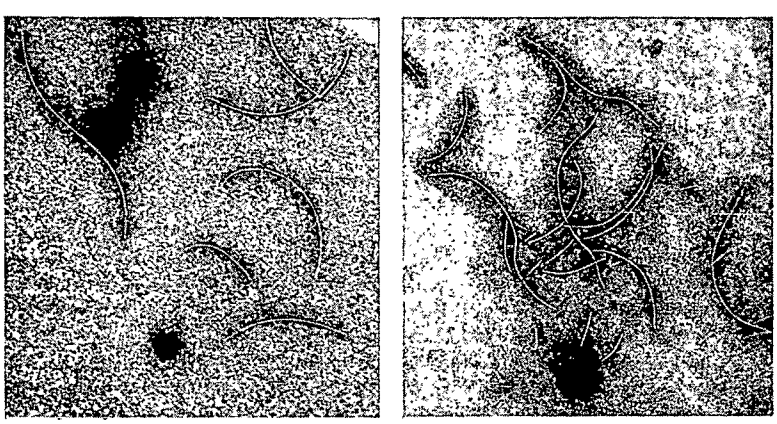
BEHAVIOUR OF ACTIVE BACTERIAL ANTIGENS DURING THE INDUCTION OF THE IMMUNE RESPONSE

(I) Properties of Flagellar Antigens from *Salmonella*

THOUGH much is known about the cellular basis of antibody formation[1], the detailed behaviour and role of antigen during the induction of an immune response are still little understood. Sabin[2] first showed that dye-protein antigens were taken up by phagocytic mononuclear cells, and investigation of the function of such cells, now usually termed macrophages, in immunity has ensued[3–10]. Both particulate and soluble antigens enter these cells[2–5], and may persist in them for many months[6]. It has been claimed that antigen in macrophages causes prolonged antibody formation and immunological memory[7,8]; alternatively, it may cause the formation of a ribonuclease-sensitive factor capable of inducing antibody formation in normal lymphoid cells[9,10]. Actually we do not know whether antigen leaves the macrophages and enters lymphoid cells capable of becoming antibody-formers. Two autoradiographic investigations[11,12] have demonstrated antigen in or on antibody-forming plasma cells, but the data do not show whether the antigen entered these cells and induced antibody formation within them or whether it merely became associated with their surface after antibody formation had already begun.

We have been struck by the fact that, in most of the foregoing experiments, milligram quantities of antigens have been used. As previous experiments from our laboratory[13] have shown that 0·01 μg of *Salmonella* antigens could cause antibody formation in rats within 3 days, we wondered how much of the antigen detected by previous workers was directly relevant to antibody production and how much to the disposal of excess antigen. To evaluate critically the role of antigen during the inductive phase we felt that: (1) the antigen to be used should be as pure and as well characterized as possible; (2) the antigen should be a 'powerful' one, so that very small quantities would induce a specific immune response; (3) the organ to be investigated should be a major site of antibody production; (4) the methods used for the detection of



antigen should be sufficiently sensitive to allow demonstration of but a few molecules or particles of antigen.

In this communication we wish to describe investigations of antigen distribution in a system meeting most of these criteria. The antigens used were various flagellar preparations from *Salmonella adelaide* bacteria, namely the intact, isolated flagella; the low molecular weight protein, flagellin, prepared by acid treatment of the flagella[14]; and a polymer prepared from flagellin by treatment with concentrated ammonium sulphate solutions. Despite the fact that iodine-131 does not give particularly good localization in autoradiographs, we chose this isotope to label our antigens. Iodine-131 has a short half-life (8·03 days), so that small quantities can be detected by autoradiography without inordinately long exposure times. Carrier-free material is available also, and trace-labelling methods have recently been devised[15,16] which allow efficient substitution without significant denaturation of proteins. The organ chiefly investigated has been the rat popliteal lymph node, where antibody-forming cells can readily be detected during a primary response to these antigens[13].

Preparation and characterization of antigens. Flagella, the first antigen, were prepared in relatively pure form by slight modifications of Koffler's[14] techniques. The method involves shearing the flagella off the bacterial bodies, and then purifying them by differential centrifugation and extensive washings. The final preparation contained no bacterial bodies when examined in the electron microscope and only trace amounts of soluble protein. Acid treatment of flagella yields a low molecular weight protein, flagellin. Flagella were brought to *p*H 1·5 with hydrochloric acid, held at room temperature for 30 min, and centrifuged at 93,000*g* for 60 min to remove a small amount of acid-insoluble material. The supernatant was neutralized and filtered through a sterilizing pad. This preparation, when chromatographed on hydroxyl apatite, shows a single protein peak. Flagellin may be polymerized by increasing the salt concentration. Flagellin solutions are brought to 60 per cent saturation with ammonium sulphate[14], held at 0° C for 16 h and centrifuged at 15,000*g* for 15 min to deposit a substantial precipitate. This pellet was dissolved in, and dialysed against, distilled water, the final solution representing polymer which we used as the second antigen. The third antigen was monomer (flagellin), which was prepared by acid treatment (as already described) of polymer. Such preparations of monomer could be repolymerized by ammonium sulphate precipitation. When used as an antigen, monomer was injected as soon as possible after preparation.

Flagella, polymer and monomer were examined for their physical and serological properties. The first feature of note is that when monomer is polymerized by ammonium sulphate fractionation, rod-shaped structures similar to the original flagella result. Figs. 1*a* and *b* are electron micrographs of flagella and polymer, stained by phosphotungstate. Both flagella and polymer preparations consist of straight or curved rods of varying lengths; more concentrated preparations of monomer examined in this way contained no such elements. Gradient density ultracentrifugation has shown that flagella and polymer are polydisperse to about the same extent. In the analytical ultracentrifuge, monomer at *p*H 1·5 (0·05 hydrochloric acid) and at *p*H 7·3 (0·1 M sodium chloride, 0·01 M phosphate buffer) showed a single peak with sedimentation constants of 1·91 and 2·25 respe[illegible]. If a molecular weight of about 30,000 for mono[illegible] and a structure for flagella and polymer similar to tha[illegible] described by Kerridge *et al.*[17] are assumed, then strands of flagella or polymer in which the ratio of length to thickness is 25 : 1, the average length found in some of our preparations, would contain about 300 sub-units. One μg of flagella or polymer would thus consist of about 1×10^{11} particles, and 1 μg of monomer, of about 3×10^{13} molecules.

The serological properties of our three antigens were examined in several ways. Rabbits were hyperimmunized with each antigen, and the resulting sera all had high and roughly equal titres of anti-flagellar antibody as measured by a serial two-fold dilution method involving bacterial immobilization[18]. Moreover, each antigen was effective in neutralizing antiflagellar antibody prepared against any of the three antigens. On a weight basis, flagella and polymer were better inhibitors than monomer, but the differences were slight. Iodination at the levels used in these experiments had no significant effect on the inhibiting capacity of the three antigens. Precipitin tests confirmed this basic similarity between the different antigens. Gel-diffusion showed one main common antigen and a second antigen present in small amounts. Immunoelectrophoresis showed one main antigen with sometimes evidence of a minor antigen. Thus the three antigens, and their iodinated counterparts, appear to consist mainly of a single antigen, present as a low molecular weight protein in monomer; as an organized structure held together by non-covalent forces in the case of polymer;

a *b*

and as an intact rod-shaped organ which also contains some acid-insoluble material in the case of flagella.

Iodination of antigens. Antigens were iodinated with carrier-free iodine-131 by slight modifications of the direct oxidation technique[16]. Monomer was more readily iodinated than were flagella. The highest specific activity achieved without alteration of antigenic specificity was 125 μc./μg of antigen, or about one atom of iodine-131 to every two molecules of monomer. This specific activity is considerably higher than that used by previous workers in this field, so that the fate of as little as 0·01 μg injected into the rat could be investigated.

Immunogenicity of the antigens. The three preparations, although consisting basically of the one antigen, showed marked differences in their capacity to induce the formation of antiflagellar antibody in adult rats. Amounts of antigens injected will be described in terms of milligrams, (mg, 10^{-3} g), micrograms (μg, 10^{-6} g), nanograms (ng, 10^{-9} g) and picograms (pg, 10^{-12} g). Rats, in groups of three, were given a primary antigenic stimulus into the hind foot-pads, the dose varying from 100 pg to 10 mg, a 10^{8}-fold range. Blood samples were taken at frequent intervals from 3 to 84 days after immunization. Serum samples were titrated for antiflagellar antibody using the immobilization method[18], both before and after treatment with 0·1 M mercaptoethanol (37° C, 1 h). This allowed us to determine the titres, respectively, of total antibody and mercaptoethanol resistant antibody. We presume, but have not proven, that the mercaptoethanol-sensitive antibody represents predominantly 19*S* macroglobulin, and the mercaptoethanol resistant antibody predominantly 7*S* γ-globulin. Figs. 2*a* and *b* illustrate the response of rats to, respectively, 10 μg and 100 ng of each antigen. The chief features of interest derived from these curves, and from examination of the data from the other six dosage-levels which will be reported in full elsewhere, are as follows:

(1) Flagella are more immunogenic than polymer, and polymer more immunogenic than monomer.

(2) These differences are much more striking during the first week after immunization than afterwards. Nearly all the antibody formed by our rats in the first week was mercaptoethanol sensitive ('19*S*'), and most of the antibody formed after 11 days, mercaptoethanol resistant ('7*S*'). Flagella were 100,000 times as powerful as monomer, and 100 times as powerful as polymer, in causing a '19*S*' primary response. By contrast, flagella were 100–1,000-fold as effective as polymer in causing a '7*S*' primary response, monomer and polymer showing little difference from each other.

(3) Remarkably low doses of antigen led to high 7*S* antibody titres. With flagella, 1 ng consistently and 100 pg occasionally caused extensive antibody formation, though peak titres were achieved only after some weeks. This finding confirmed the earlier work of Fitch and Winebright[19]. Increasing the dose above 1 μg had little effect on the immune response.

(4) With all 3 antigens, peak titres were maintained for many weeks.

One possible reason for the greater immunogenicity of flagella is that these preparations are more heavily contaminated with traces of somatic *O* antigen, which has known adjuvant properties. Surprisingly, however, we could demonstrate no significant difference in *O*-immunogenicity between the three preparations. The persistence of traces of *O* antigen in extensively purified monomer remains a puzzling feature.

The distribution of these antigens in the host animal will be discussed in Part II of this communication. The chief conclusions arising from both Parts I and II will be summarized at the end of Part II.

(II) Cellular Distribution of Flagellar Antigens labelled with Iodine-131

In Part I of this article, the preparation and properties of antigens from *Salmonella* flagella have been described. These were labelled with carrier-free iodine-131; this section describes their cellular distribution in the rat following injection via the hind foot-pads.

Distribution and persistence of antigens in various organs. Labelled antigens were injected into the hind foot-pads of rats in doses of 70 ng–10 μg. Rats were killed at intervals of 5 min–72 days after injection. Lymph nodes (popliteal, aortic, inguinal and mesenteric), thymus, liver, spleen and thyroid were removed and weighed, and serum samples were prepared. Radioactivity was determined by counting γ-rays with a sodium iodide crystal. Fig. 3 shows the specific activities of the popliteal and aortic lymph nodes, liver, and spleen in a representative experiment where 10 μg of labelled flagella (170 μc., iodine-131) was injected. Other organs, with the exception of thyroid, showed minimal labelling. It can be seen that the radioactivity, per wet weight of tissue, is far higher in the popliteal node than elsewhere. The next lymph node draining the injection site, namely the aortic node, showed significant, though considerably less, labelling. Specific activities in liver and spleen were less than 1 per cent of those achieved in popliteal nodes. In all these organs, there was a marked tendency of radioactivity to persist for long periods. Fig. 4 is a composite representation of several experiments to illustrate the differing degrees of persistence of different labelled proteins in popliteal nodes. The proteins used were: 2 different doses (10 μg and 70 ng) of flagella; 2 doses (10 μg and 100 ng) of monomer; and 1 dose (10 μg) of the virtually non-antigenic protein, homologous rat serum albumin. Results are expressed as the percentage of the injected radioactivity found in the popliteal nodes at various times after injection. The most antigenic material, flagella, was trapped to the greatest extent in the popliteal nodes. It also persisted most markedly, the biological half-life in the nodes being 3 weeks. Monomer, a less-efficient antigen, was trapped and retained less efficiently, the half-life in the nodes being 1 week. Rat serum albumin was poorly trapped by the nodes, and also had a short half-life. Despite a 150-fold variation in total dosage, the percentage of the injected antigen retained in the nodes is remarkably constant from animal to animal and from experiment to experiment.

Cellular localization of labelled antigens in popliteal lymph nodes. Autoradiographs of sections, and occasionally cell smears, from the various organs were prepared

Regression lines fitted according to the method of least squares

using Pelc's[20] technique and Kodak '*AR* 10' stripping film. Chief attention was focused on the popliteal nodes. The key findings of this part of the investigation were as follows:

(1) Macrophages took up and retained large quantities of antigen.

(2) Lymphoid follicles became heavily labelled with antigenic proteins but not with rat serum albumin. Many of these follicles retained label avidly, and developed into typical germinal centres.

(3) Plasma cells formed as a result of the injection of the labelled antigens showed a remarkable paucity of labelling.

Fig. 5 is a tracing of a section through a normal unstimulated rat popliteal lymph node, somewhat schematized. Lymph enters via the peripheral circular lymph sinus, 'percolates' through the cortex, enters the medullary areas and leaves via the efferent vessels. The cortex contains much diffuse lymphoid tissue, but also discernible rounded collections of small lymphocytes, without detectable germinal centres, the lymphoid follicles. The cortex contains only occasional scattered macrophages, but the layer of reticular cells forming the inner wall of the circular sinus appears to have phagocytic properties (*vide infra*). The medulla of normal nodes can be arbitrarily divided into 'dense' and 'loose' areas. The dense areas contain large numbers of macrophages and mast cells. The looser areas contain the lymph sinuses, scattered macrophages and mast cells and a very small number of plasma cells. In this area, particularly adjacent to the diffuse cortical tissue, plasma cells develop during the immune response.

Five min after injection of iodinated flagella, heavily labelled macrophages can be seen in the medulla. At 30 min, this labelling is more intense and diffuse, and specific labelling can also be seen in the littoral phagocytes of the circular sinus. By 2 h the first traces of label have

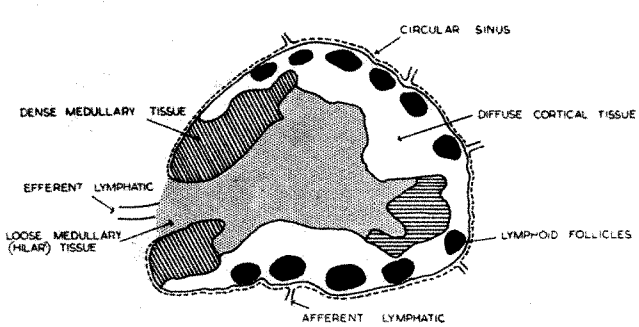

Fig. 5. Schematic diagram of a section through the rat popliteal node

entered the lymphoid follicles, though this localization is much more striking after 24 h when all the lymphoid follicles of the node are heavily and specifically labelled. Fig. 6 is a low-power view of a popliteal node section 24 h after the injection of 10 μg (170 μc. iodine-131) of labelled flagella. The labelling pattern over the follicles is not uniform, but frequently reticulated or variegated, suggesting that the label may be between rather than in the lymphocytes. Smears in which the cells are separated from each other show that most of the label is not in or on the lymphoid cells. We postulate, though without firm evidence, that this label is in cytoplasmic extensions (dendritic processes) of specialized macrophages pre-existent in the lymphoid follicle. At this, as at all subsequent times, the diffuse cortical lymphoid tissue is virtually unlabelled.

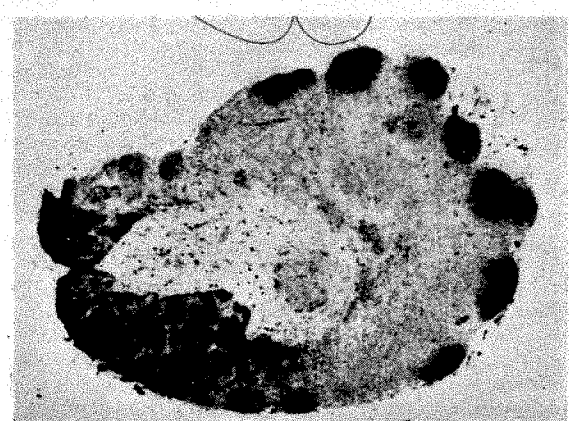

Fig. 6. Autoradiograph of popliteal lymph node section 24 h after injection of 10 μg of labelled flagella (170 μc. iodine-131). Note heavily labelled lymphoid follicles and medulla (×*c.* 51)

By 2 days, the diffuse cortical tissue showed increased cellularity, with an increase in the number of scattered but unlabelled blast cells. By 3 days, accumulations of primitive cells could be seen lying immediately deep to the labelled follicles, and frequently appeared to compress the originally rounded collection of grains into a crescentic shape. By 5 days these primitive cells had formed a typical young germinal centre (Fig. 7). The appearances suggested that germinal centres arose by invasion of pre-existent labelled follicles by blast cells arising in the diffuse cortical tissue, and not, as had generally been believed, by division of primitive cells in the centre of the pre-existent follicle. Possibly many of these blasts migrate to the medulla. At 5 days, extensive sheets of plasma cells, many of them still immature, could be seen in the medulla of the nodes and most of these had become typical mature plasma cells by 8 days. Figs. 8*a* and *b* show two areas in the medulla of a single lymph node taken 8 days after the injection of 70 ng (8·3 μc. iodine-131) of labelled flagella. The areas were about 1 mm apart in the section. The extremely heavy labelling of the macrophages (Fig. 8*a*) contrasts strongly with the virtual absence of label over the antibody-forming plasma cells (Fig. 8*b*). Cell smears confirmed that most plasma cells showed only background labelling.

Over the next few weeks, the general cellularity of the nodes decreased somewhat, but labelled lymphoid follicles, many of them now showing prominent germinal centres, remained an outstanding feature. Medullary cords with only slightly diminished numbers of mainly unlabelled plasma cells could be seen throughout. Macrophages remained heavily labelled, and 4 weeks after antigenic stimulation, many mast cells also showed specific, heavy labelling.

The sequence of events following the injection of labelled monomer differed in a number of important respects. Though extensive phagocytosis by macrophages also

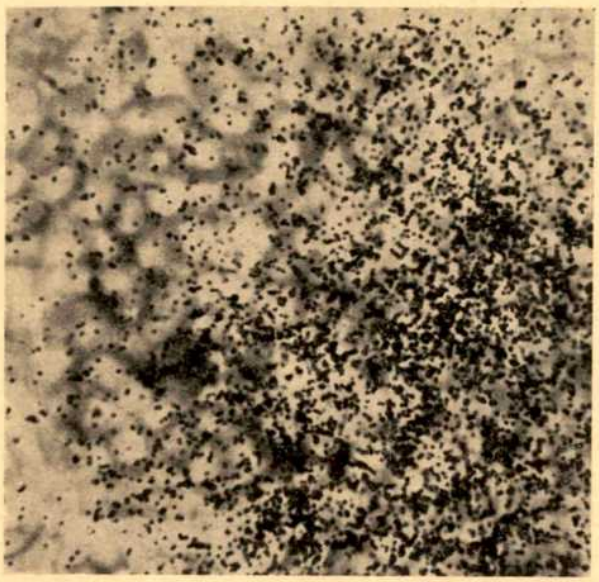

Fig. 7. Autoradiograph of popliteal lymph node section 5 days after injection of 70 ng of labelled flagella (8·3 μc. iodine-131). Note heavily labelled lymphoid follicle (right) and lightly labelled germinal centre (left). (×1,000)

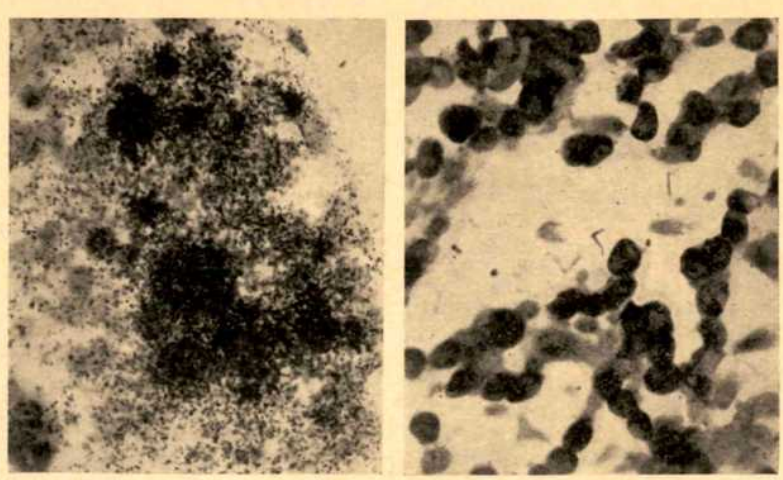
occurred rapidly the low-molecular weight antigen diffused more extensively throughout the cortical tissue. Specific labelling of lymphoid follicles occurred later, was less marked, and more variable. Plasma cells appeared much later (10–14 days), and macrophage labelling decreased more rapidly. Germinal centres were prominent at 14 days and remained so for some weeks.

Labelled homologous rat serum albumin (9 μg protein, 120 μc. iodine-131) was detected in large amounts in the node 1 h after injection; the label was scattered diffusely throughout the node but tended to be heavier in medullary areas. Within 24 h the amount of label decreased rapidly, only small quantities being retained by macrophages. At no stage did selective localization occur in the lymphoid follicles.

To examine quantitatively the presence of labelled antigen in the lymphoid follicles and medullary macrophages, visual grain counting was performed. As labelling of lymphoid follicles was somewhat variable, especially with small doses of antigen, it was decided to count a random area of each follicle seen in a section, using an eye-piece graticule. By contrast, as the medullary labelling was usually very uneven, it was felt that a subjective element in selecting medullary areas for counting could not be avoided. Thus 2 medullary areas, from each section, each considered to have a median degree of labelling, were selected for grain counting. The results in the case of an experiment using 70 ng of labelled flagella are shown in Table 1. Counts are expressed per 1,000 μ^2, an area usually comprising about 40 small lymphocytes or 15 medullary macrophages. Within 2 h after antigen injection, medullary labelling appears to reach a peak while localization in lymphoid follicles is barely detectable. After this period, the amount of label in the medulla appears to stay relatively constant whereas label in the follicles continues to rise for a day or more. Between 8 and 28 days, labelling in both areas fell slowly.

The autoradiographic results are consistent with the following picture. Two sorts of macrophages exist in the lymph node. Medullary macrophages take up all proteins

Table 1



Time killed after injection of antigen	Mean grain count of follicles	Mean grain count of medulla
5 min	2	38
30 min	2	182
2 h	24	168
4 h	38	149
24 h	42	166
3 day	73	186
5 day	63	230
8 day	62	180
14 day	32	124
28 day	46	185

Grain counts from autoradiographs of sections of popliteal nodes from rats at various times after injection of 70 ng of labelled flagella (8·3 μc. iodine-131). All counts refer to areas of 1,000 μ^2. The follicle counts represent the mean values of all follicles in one randomly chosen section from each node. The medulla counts represent the means of two areas with apparent average numbers of grains. Each count was adjusted to allow for decay of isotope. The adjusted counts over diffuse cortex were background level (about 5 grains).

used but retain avidly only the bacterial antigens. More specialized, dendritic macrophages in the lymphoid follicles take up only the bacterial antigens and thus appear to exhibit some capacity to recognize 'foreignness'. The presence of antigen in the node somehow causes the appearance of blast cells in the diffuse cortical tissue. Some of these collect immediately deep to the antigenic depot in the lymphoid follicle and form a germinal centre. Meanwhile, primitive plasmablasts appear in the medullary cords and in time develop into antibody-forming cells. It is tempting to think that germinal centre formation in the cortex and plasma cell formation in the medulla are related in some way, particularly during the period of '7*S*' antibody formation, but evidence for this is lacking. The plasma cells formed as a result of antigenic stimulation are largely unlabelled. From the dose of antigen given and the distribution of label in the node, it can be calculated that antibody-forming cells contain a smaller (and possibly much smaller) number of antigen-derived amino-acid residues than there are ribosomes in the cell. This suggests that antibody formation is not due to a direct template mechanism. Immune induction may involve a transfer of some material from macrophages to primitive lymphoid cells, which have perhaps been rendered more reactive in some way. This material might be minimal quantities of antigen acting as an inducer or a nucleic acid fraction.

Our findings from Parts I and II may be summarized as follows:

(1) We have described an antigen which exists in three different physical states: as a monomer, as an organized polymer, and as the native, bacterial flagellum. Though the three preparations show little difference in their *in vitro* immunoligical behaviour, they differ markedly in

a *b*

Fig. 8. Autoradiographs of two adjacent areas in the medulla of the same popliteal lymph node section, 8 days after the injection of 70 ng of labelled flagella (8·3 μc. iodine-131). *a*, Shows heavily labelled macrophages; *b*, shows absence of label in plasma cells

their capacity to cause antibody formation, particularly '19*S*' antibody formation, *in vivo*.

(2) As 100 ng of flagella is virtually a maximal primary antigenic stimulus, the use of larger amounts introduces the danger of obscuring the basic problems of immune induction.

(3) This consideration makes it essential to use, as a label, a carrier-free isotope of short half-life.

(4) Although the popliteal node traps less than 1 per cent of antigen injected into the foot-pad, the specific activity of this organ is 100 times higher than that of organs such as liver and spleen, which were commonly used in this type of investigation by previous workers. With critically small doses of antigen, the cellular distribution of labelled material is thus best investigated in the popliteal node.

(5) Flagella are trapped and retained by the popliteal nodes to a greater extent than is monomer.

(6) Antigens (flagella and monomer) are primarily localized in macrophages and lymphoid follicles. A minimally antigenic protein, such as homologous serum albumin, shows slight localization in macrophages but none in lymphoid follicles.

(7) Plasma cells resulting from antigenic stimulation show little or no labelling.

We feel that the system here described will prove to be valuable in quantitative investigations on the role of antigen in various immunological events. The work reported will be published in detail elsewhere. Present investigations are also directed towards the role of the antigen in immunological memory, in immunological tolerance and the general problem of neonatal incompetence and in immunological paralysis.

A NEW REPEAT STRUCTURAL ELEMENT OF MITOCHONDRIAL AND CERTAIN CYTOPLASMIC MEMBRANES

By Prof. FRITIOF S. SJÖSTRAND
Department of Zoology, University of California, Los Angeles

THE mitochondrial outer surface membrane as well as inner membranes are paired structures with two membrane elements forming the outer membrane as well as each inner membrane. Each constituent membrane element appears triple-layered after potassium permanganate fixation, as shown by Robertson[1], who has included the mitochondrial membrane elements as part of his unit membrane system.

The same triple-layered unit membrane structural pattern has been observed in the α-cytomembranes ("rough-surfaced membranes") and the Golgi membranes ("smooth-surfaced membranes").

The triple-layered structure of the unit membranes has been assumed to reflect their basic structural feature, a bimolecular leaflet of lipids sandwiched between two thin layers of protein (or of non-lipid material), according to the membrane model by Danielli and Davson[2], Robertson[3], and myself[4,5].

At the Gordon Research Conference on "Structure and Function of Multilayer Systems in Cells", June 1962, as well as at the International Electron Microscopy Congress in Philadelphia, August 1962, I presented material indicating a more complex membrane structure in mitochondria and in certain cytoplasmic membranes. After osmium fixation and section staining, each membrane element appears triple-layered, but a considerable amount of the material in the middle light layer is stained. The total thickness of the triple-layered membrane element is about 50 Å, corresponding to the thickness of the single osmiophilic layer observed in the classical osmium-fixed material that had not been section-stained.

After potassium permanganate fixation, the mitochondrial membrane elements show a more complex structural pattern with opaque layers at the two surfaces of each membrane element and opaque cross-bridges connecting these surface layers (Fig. 1). The membrane elements appear to consist of minute globular components with a diameter of about 50 Å. The patterns observed both in cross-sections and tangential sections through the membrane elements could be interpreted on the same basic assumption that the membrane represented a two-dimensional aggregate of globular particles.

Smooth-surfaced cytoplasmic membranes in the tubular cells of the kidney show the same structural pattern as the mitochondrial membrane elements (Fig. 1). However, the total thickness of these membranes is distinctly greater (60–70 Å) than that of the mitochondrial membrane elements as is obvious from the direct comparison of the dimensions which can be made on pictures where they are located side by side.

The plasma membrane appears geometrically asymmetric, triple-layered[6–8] after section staining of osmium-fixed and mostly also of potassium permanganate-fixed tissue. The stained cytoplasmic layer is thicker and frequently also more intensely stained than the peripheral opaque layer.

In the material discussed here, the plasma membrane in the potassium permanganate-fixed material appears triple-layered without any such sub-structure observed in the mitochondrial and cytoplasmic membranes. The total thickness of the plasma membrane (90 Å) furthermore exceeds that of both the mitochondrial membrane element and the cytoplasmic membranes (Fig. 2).

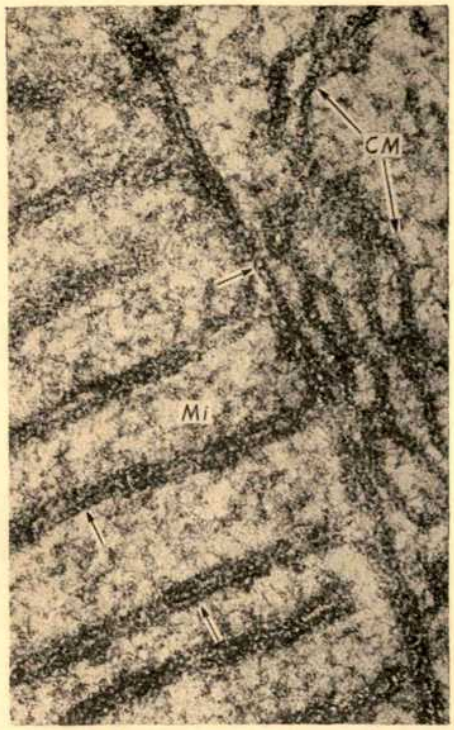

Fig. 1. Part of mitochondrion (*Mi*) and some cytoplasmic membranes (*CM*) in potassium permanganate-fixed mouse kidney. Arrows point to regions where membrane elements are favourably oriented to reveal the globular substructure. (×200,000)

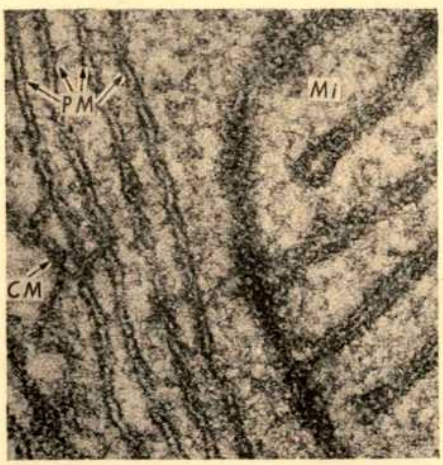

Fig. 2. Part of mitochondrion (*Mi*), some cross-sectioned plasma membrane (*PM*), and some cytoplasmic membranes (*CM*). Notice the difference in dimensions between mitochondrial membrane elements and the plasma membrane. The plasma membrane appears symmetrical owing to incomplete staining. In spite of this the difference in dimensions is clearly shown. (×200,000)

Recent observations made on frozen-dried pancreas tissue[9] support the conclusion that certain types of membranes are characterized by a globular substructure.

The cytoplasm of the exocrine pancreas cells is filled with α-cytomembranes between mitochondria, Golgi regions, and in the apical cell region, zymogen granules. Any section through an exocrine pancreas cell, therefore, will cut through a large number of cytoplasmic membranes at different orientations—transversally, obliquely or tangentially. This simple cytology of the exocrine cells is very helpful when trying to identify structural components in frozen-dried material with its low contrast and with contrast patterns which are different from the conventional ones observed after chemical fixation.

In cross-sections at low magnification the various membranes appear as a light line according to the description by Sjöstrand and Baker[10]. In the mitochondria each membrane element is represented by one such light line with a thickness of 40–50 Å. In areas in the cytoplasm where such light lines are absent, the membranes must be tilted in relation to the plane of the section since no parts of the cytoplasm of these cells are lacking membranes. In such areas where the membranes must be oriented more or less parallel to the plane of the section a very regular crystalline-like pattern can be observed (Figs. 3 and 4). This pattern seems to consist of regularly arranged rows of lightly stained or unstained particles, the individual particles being separated by more intensely stained material. These rows alternate with rows of intensely stained spots which range in diameter between 10 and 20 Å. The separation between the centres of the parallel rows of light particles is 45 Å.

Since the dimensions of the globular substructure are similar in both potassium permanganate-fixed and in the

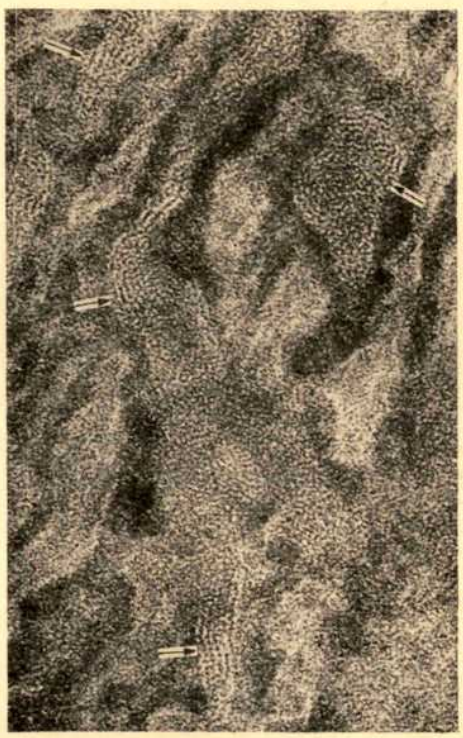

Fig. 3. α-cytomembranes in exocrine cell of the mouse pancreas fixed by means of freeze drying. The orientation of the membranes in relation to the plane of the section varies considerably. When the membranes have been sectioned obliquely a regular pattern of globular sub-units arranged in rows can be seen (arrows). (×200,000)

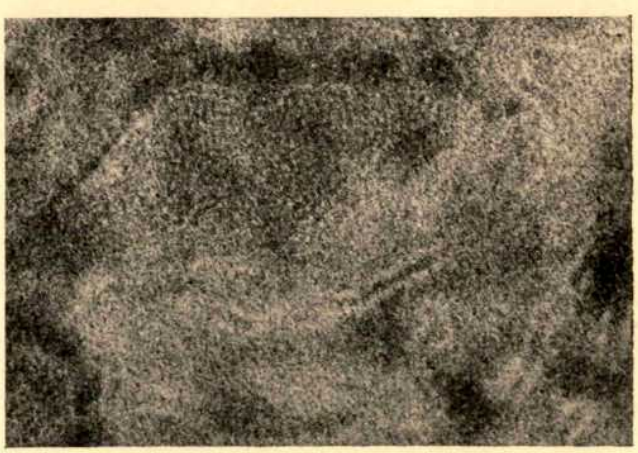

Fig. 4. Close-to-focus picture of mitochondrion in frozen dried exocrine pancreas cell. Some mitochondrial membranes are oriented perpendicular to the plane of the sections. In the upper part of the picture mitochondrial membrane oriented parallel to the plane of the section showing a granular pattern. (×300,000)

frozen-dried material, and since the dimensions correspond to the total thickness of these membranes, it is assumed that both methods of preparation reveal the same structural components. In frozen-dried material the arrangement of globular sub-units is frequently strikingly regular. This regularity has not been observed in potassium permanganate-fixed material. We would, however, expect a higher probability for distortion of such a pattern in connexion with chemical fixation than during freeze-drying.

The fact that a similar sub-structure can be observed in both permanganate-fixed and frozen-dried material makes it justifiable to discuss this structural pattern as possibly a real pattern reflecting the structure of these membranes in the living cell.

Recently (at the Biophysical Society meeting in San Francisco), Robertson reported having observed a sub-structure showing a geometric regularity in the plasma membrane confined to certain special localized contact regions (presumably synaptic) in the central nervous system of the goldfish. The two plasma membranes in contact in those regions are closely packed. This pattern was not observed in other parts of the plasma membrane. He also observed a similar pattern in the isolated disk membranes from the outer segments of retinal rods. The pattern observed in the investigation reported here has not so far been observed in the plasma membrane.

This structural pattern is not related to the globular structure observed by Fernández-Morán[11], Parsons[12], and Stoeckenius[13] in fragmented negatively stained mitochondria. The globular components observed by that technique are of a different size (about 80 Å in diameter) and represent globular components associated with the surface of transformed and fragmented mitochondrial membrane material.

The interpretation of this structural pattern in terms of molecular architecture is difficult considering the uncertainties with respect to what appears stained in the patterns. Tentatively, it is proposed that the observed patterns reflect a regular arrangement of globular units or micelles consisting of lipids. The membrane would then contain as a basic structural component lipids in a globular form like a two-dimensional flocculated emulsion. Between the lipid globules protein molecules are arranged in rows and also extend between the rows, thereby delimiting the territories of the individual lipid globules. This protein structure would represent the stabilizing factor which would prevent the lipid globules from fusing to form either a bimolecular leaflet or large lipid droplets.

With respect to the mitochondrial membrane elements, it is tempting to propose that the components of the electron transport chain constitute at least part of the proteins of the membrane element, that they are kept in orderly array between the lipid droplets and, with respect to movement, are more or less restricted to rotational movement by this association.

SOLUTE AND WATER ABSORPTION BY THE HUMAN SMALL INTESTINE

By Dr. HAROLD P. SCHEDL* and Dr. JAMES A. CLIFTON

State University of Iowa, Department of Medicine, University Hospitals, Iowa City

INTESTINAL absorption was studied in normal subjects and patients with non-tropical sprue by transintestinal intubation[1]. Solutions pumped into the nasal end of the tube at 15 ml./min entered the gut through a proximal hole in the tube (Fig. 1). After perfusing the intestine the intraluminal contents are sampled through an opening 15 cm distal to the entry site by siphonage from the anal end of the tube. As the tube progresses distally, the entire small intestine is studied as segments of gut included between solution entry and sample exit holes 15 cm apart[2]. A steady-state is reached after 30 min of perfusion. Net transfer is measured by analysis of intraluminal contents. Transfer of a component is calculated from the difference between initial concentration in the solution perfused and final concentration in the sample of perfusate. Net fluid transferred is corrected for by the non-absorbed indicators polyethylene glycol (PEG) and phenol red. The relation of initial to final non-absorbed indicator concentration, $C_{initial}/C_{final}$, is the volume in the bowel lumen relative to the volume infused at the time the sample is obtained. During each investigation at least three successive 5–15 min samples are collected. Transfer rates during each of these periods are similar, in agreement with steady-state kinetics, and the data are means of rates of the periods. The bowel lumen is the point of reference. Addition to the luminal contents (secretion) is designated by numbers greater than 0, and subtraction from the bowel contents (absorption) by numbers less than 0.

* Holder of the Lederle Medical Faculty Award.

Sodium and potassium are analysed by internal standard flame photometry, chloride by amperometric titration, osmolality by freezing-point depression, glucose by glucose oxidase and PEG turbidimetrically[3]. Phenol red analysis and the preparation of Ringer's and glucose-Ringer's solutions have been described[2,4].

Transfer data are calculated as follows:

Net transfer, m.mole/l. =
(Initial conc., m.mole/l.) −
(final conc., m.mole/l.) $\left(\frac{C_{initial}}{C_{final}} \text{ of indicator}\right)$

Net transfer, m.mole/h. =
net transfer, m.mole/l. (vol. perfused, l./h)

Transfer data obtained during distilled water perfusion are given in Table 1. Secretion of sodium and chloride is observed in both normal subjects and the patient with non-tropical sprue. A consistent proximal to distal gradient is not observed in the normals. Secretion of sodium and chloride in a normal is lower in the colon than in the small intestine. Potassium secretion in both small intestine and colon is low, although colonic rates are slightly higher. In normal subjects, absorption of water is greater in the proximal small gut. In the patient with sprue, absorption of water is the same throughout the small gut, but secretion of sodium, chloride, potassium and total solute shows a slight distal increase. The sum of net transfers of sodium, chloride, and potassium

(Σ column) approximates net transfer of total solutes (mOSM column).

* Net transfer is the resultant of secretion (entry into the gut) and absorption (exit from the gut) during steady-state perfusion of the indicated solutions. Secretion increases gut contents and is indicated by numbers greater than zero. Absorption decreases gut contents and is indicated by numbers less than zero.

† Calculated as 100 (indicator ratio 1:1), where PEG and phenol red are the indicators, and the ratio is that of initial to final indicator concentration.

‡ Algebraic sum of the transfer of Na^+, Cl^-, and K^+.

§ Sum is calculated assuming that the chloride transfer, which was not determined, is equal to the sodium transfer.

‖ Colon.

Small intestinal transfer data derived from perfusion of Ringer's solution are given in Table 2. Sodium concentration in Ringer's (approximately 145 m.equiv./l.) is essentially the same as in extracellular fluid (ECF). Chloride concentration (approximately 150 m.equiv./l.) provides a 45 mM. gradient for chloride absorption. In normal subjects, water, sodium, chloride and potassium are absorbed proximally and secreted distally. Total transfer rates are much lower than with distilled water (Table 1). In the patient with non-tropical sprue, water, sodium and chloride are secreted proximally and absorbed distally, that is, the net transfer relationship of proximal to distal small intestine is the reverse of normal in the absorption and secretion rates are great. The sum of normal subjects under these con[illegible] the net transfer net transfers of electrol[illegible] of total solutes.

¶ See Table 1 for footnotes.

Transfer data from 1 per cent glucose-Ringer's solution in Table 3 show absorption throughout the small gut in normal subjects. (The changes in net potassium transfer are small, and there is a small distal secretion.) The gradient is marked: absorption of water, sodium, chloride, glucose, and total solute is very high proximally and progressively decreases distally. The concentrations of sodium and chloride are 27 mM lower in 1 per cent glucose-Ringer's than in Ringer's. This reduces correspondingly the gradient from bowel lumen to ECF for chloride absorption. Sodium concentrations are essentially equal between ECF and Ringer's (Table 2), but now have a 27 mM gradient for secretion from ECF to glucose-Ringer's in the bowel lumen. Despite reduction in the chloride and reversal of the sodium absorption gradients, absorption is much greater from 1 per cent glucose-Ringer's than from Ringer's, even though both are isotonic.

In contrast with the normal subjects, the patient with non-tropical sprue again shows high absorption distally. Distal absorption in sprue with glucose-Ringer's is as great as proximal in normal subjects. Secretion occurs in the proximal small gut of the patient with sprue even with glucose-Ringer's, although it is lacking throughout in normal subjects, except for a low distal potassium secretion.

Net transfer by the small intestine during perfusion with distilled water and Ringer's solution is the resultant of concentration gradients between bowel lumen contents and ECF. Thus, high rates of sodium and chloride and low rates of potassium secretion during distilled water perfusion parallel concentration gradients (Table 1). With Ringer's solution, normal subjects show little net transfer in agreement with minimal gradients (Table 2). The thermodynamic activity gradients of water and ions between ECF and Ringer's solution is minute by comparison with the ECF-distilled water gradient that promotes secretion of solute and absorption of water. The small gradient for chloride accounts for the slight absorption in the proximal gut. If the proximal small gut were more permeable than the distal, the proximal absorption of sodium and chloride would be explained. A low rate of distal secretion of sodium, chloride and potassium is observed.

Concentration gradients cannot explain absorption from 1 per cent glucose-Ringer's. Proximal sodium and chloride absorption is much greater than predicted from data with Ringer's. Despite the decrease in chloride gradient, chloride absorption increased 3–5-fold. Sodium absorption increased [illegible]-fold despite the change from Ringer's to a gradient for sodium secretion to no gradient glucose-Ringer's. Rates are remarkably high: one-third of the total solute and water are absorbed. The transported solutes comprise a little less than one-third of the total sodium and chloride and more than half the glucose perfused. The high sodium and chloride absorption is related to the presence of glucose, since it does not occur without glucose. Glucose, sodium and chloride are absorbed in equimolar proportions, and appear to be inextricably linked in their transport under the conditions of study.

Bulk solution other than that perfused could enter the perfusion zone either through secretion by the mucosa of this region or by entry from above or below. The final concentration of non-absorbed indicator would be lowered by these entering bowel fluids. Absorption of components of entering fluids, for example, water, sodium and chloride, would be underestimated. Thus, even during high absorption, if a slightly higher rate of secretion of such extraneous fluids were to occur, only a slight secretion would be detected. For this reason the terms 'net transfer', 'absorption', and 'secretion' do not indicate sources of transported materials, but refer merely to the resultant of the total process. Since isotopic data are not presented, fluxes are not relevant to this discussion.

During absorption of sodium, chloride and glucose in concert, bulk entry of solution other than that perfused would distort interrelationships. Such contaminating solutions would contain higher sodium concentrations than 1 per cent glucose-Ringer's and lack glucose. This would oppose the demonstration of simultaneous sodium and glucose transport: dilution of glucose would be detected by change in indicator concentration, glucose transport would be estimated reliably, but net sodium transport would be underestimated. Extraneous sodium could not be differentiated from that infused. Since simultaneous sodium and glucose transport is demonstrated, the role of this artefact must be considered.

The following argument supports the contention that bulk entry of extraneous solution influences data in normal subjects only minimally at the infusion rate of 15 ml./min.

** Water injected to unplug tube and obtain samples.

During fasting, 7–8 l. of fluid are secreted into the small intestine each day. Assuming even distribution over the 24 h, this is an entry-rate of 4·9–5·5 ml./min. If it is further assumed that this secretion rate is evenly distributed over the 3 m of small gut, and the perfusion area is but one-tenth to one-twentieth of total small bowel, the contribution of non-perfused bulk solution would approximate at most 0·5 ml./min. The method is of the order of magnitude of errors inherent in the method and is less than cumulative results from several [illegible]. Actually, on the average the volume of fluid present intraluminally at any one time must be greater in the proximal than the distal small gut, since most of the secretion originates proximally. Continuous absorption by the gut, and the predominance of high absorption rates in the proximal gut would further contribute to an average proximal intraluminal volume greater than the dis Thus there should be a greater interference by extrane solutions in the proximal small gut. Nevertheless, c current transport of sodium, chloride and glucose equimolar proportions is readily demonstrated. Th there is at least enough sodium absorbed to give equimolar relation between sodium and glucose transp It cannot be excluded that, as a result of errors of unc estimating sodium absorption, absorption of sodium excess of glucose might not occur.

con[illegible]n though this source of error is present in relat transpo[illegible]ransport, conditions of greater and lesser by this techn[illegible]ous substances are readily defi of at least three [illegible]e each rate is the mean of ra inherent error of underest[illegible]ch agreed quite well, t present in the bowel causes study. Artefact from this source [illegible]ption of substan in normal subjects. [illegible]ation during

Certain data on a patient with sprue are n[illegible] minir with findings in normals. Thus, with Ringer's, h proximal secretion occurs in the presence of a small c centration gradient for absorption. The distal absorp rate is so much greater than normal that increased meability, prolonged gut contact time, or an electro conservation mechanism are suggested. Furtherm the patient with sprue shows dissociation of sodium chloride from glucose transport. Thus, with gluc Ringer's, high proximal rates of sodium and chlo secretion occur during low rates of glucose absorpt Increased entry of extraneous solution into the perfu area shown by the increase in net intraluminal vol explains this. Increased permeability or impairmen sodium conservation in the proximal gut in sprue allo leak of sodium down its concentration gradient ma present. In the distal small gut, sodium, chloride glucose absorptions are equimolar and are as high as proximal small gut in normals.

During perfusion of the colon with distilled w sodium and chloride, secretions are lower but potass secretion is higher than in the small intestine. Ringer's, sodium is absorbed, potassium secreted. accords with the finding of sodium retention and potass secretion by the colon[5] and suggests a colonic permeab lower than that of the small intestine to the ionic gradi produced by distilled water, despite a longer contact under conditions we have used.

Net transfer in the small intestine in normal sub and patients with non-tropical sprue has been studie

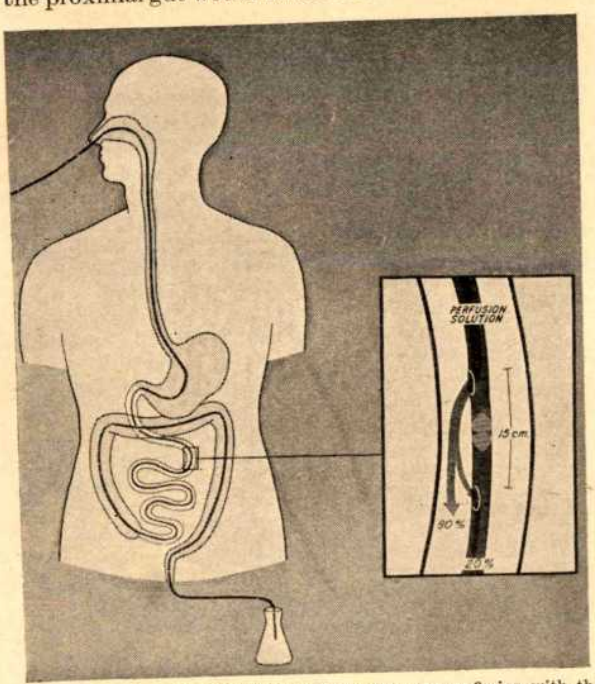

Fig. 1. Technique for investigating absorption by perfusion with the transintestinal tube. Steady-state perfusion of the small intestine is induced by pumping solution into the bowel through the proximal hole in the transintestinal tube at 15 ml./min. The solution enters at a known distance from the nares, and the perfusate is sampled 15 cm distal to the entry site by siphonage from the anal end of the tube. A solid metal connector separates entry from exit holes

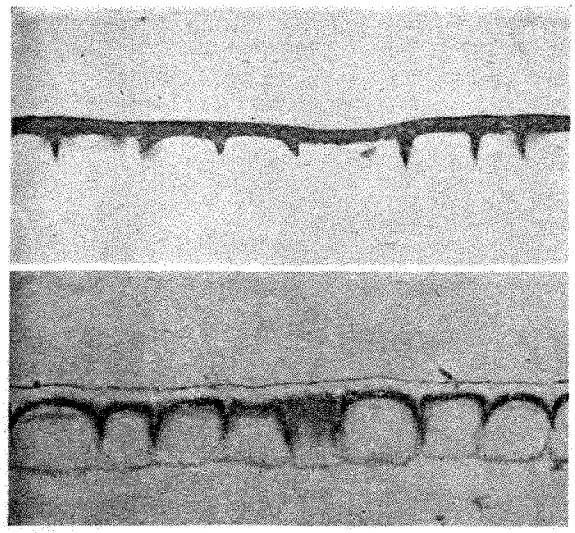

Fig. 1. Cuticular membranes of leaf of *Euonymus japonicus* L. *A*, cutin, stained with sudan IV; *B*, pectin near epidermal cells, stained with ruthenium red

obtained from minced leaves but the method of separation suggests that they were derived from the leaf cutin. Our limited information on the nature of cutin raised the question of the extent to which the cutin of plants is constant in composition. An examination was therefore made of the cutin of leaves and fruits of different species.

Isolation of cuticular membranes and constituent acids. Cutin was obtained, in large-scale preparations, from fruits of apple (Dabinett cider variety) and gooseberry (var. Careless) and leaves of *Euonymus japonicus* L. (an evergreen shrub), selected because of their well-developed cuticles. The apple fruits were boiled in water to loosen the skins, which were then boiled in successive portions of 1 per cent sulphuric acid to free them from flesh. The cuticular membranes were extracted with methanol to remove waxes, and dried. The gooseberry fruits were shaken with heptane–methanol to remove surface waxes, and the skins were separated from the flesh by hot water and acid treatment. The membranes obtained were extracted with methanol, treated with zinc chloride–hydrochloric acid solution to remove adhering remnants of epidermal cells, washed with dilute sodium carbonate solution, water, alcohol and dried. The *Euonymus* leaves were extracted with ether to remove waxes, and laminæ cut from the leaves were treated with ammonium oxalate–oxalic acid solution[5,19] to liberate the cuticular membranes. These were treated with zinc chloride–hydrochloric acid solution, washed and dried.

Cutin in the membranes from apple fruits was saponified, at room temperature, with 3 per cent ethanolic potassium hydroxide. The alkaline extract was almost neutralized, precipitated salt was removed, and the alcohol was taken off under reduced pressure. Acids liberated on acidification were extracted with ether, washed out with potassium bicarbonate solution, and again taken up in ether. The pale yellow solid (19 g) obtained on removal of the solvent was dissolved in a minimum amount of ethyl acetate. On keeping the solution in the refrigerator, two crops of crystals were obtained and recrystallized to constant melting points from ethanol–petroleum ether (compounds I and II). Infra-red analysis showed them to be hydroxylated acids; equivalent weights were determined by titration of benzene–methanol solutions, under nitrogen, with potassium methoxide[20]. Compound I was shown to be a saturated acid, m.p. 99°–100° (found: C, 64·9; H, 11·1 per cent; equiv. 324: calc. for $C_{18}H_{36}O_5$: C, 65·0; H, 10·9 per cent; equiv. 332). The m.p. was undepressed by admixture with 9,10,18-trihydroxyoctadecanoic acid, m.p. 102°–103°, kindly supplied by Dr. M. Matic. Compound II also was a saturated acid, m.p. 75°–76° (found: C, 66·1; H, 11·3 per cent; equiv. 292: calc. for $C_{16}H_{32}O_4$: C, 66·6, H, 11·2 per cent; equiv. 288). The m.p. was undepressed by admixture with 10,16-dihydroxyhexadecanoic acid, m.p. 76°, supplied by Dr. Matic. Compound I amounted to 25 per cent and compound II to 15 per cent of the ether–soluble acids obtained from the apple fruit cutin; in comparison, Matic[17] found 43 per cent of 9,10,18-trihydroxyoctadecanoic acid (compound I) in the *Agave* acids. The residual fraction of the apple ether-soluble cutin acids was an oil which showed additional hydroxy-fatty acid components and some unsaturation.

10,16-Dihydroxyhexadecanoic acid crystallized readily from the ethyl acetate solution of the ether-soluble acids (4·9 g) isolated from the gooseberry fruit cutin, and comprised more than 70 per cent of the acids obtained. The *Euonymus* leaf ether-soluble cutin acids (27 g) yielded both 10,16-dihydroxyhexadecanoic and 9,10,18-trihydroxyoctadecanoic acids, but in differing proportions from those obtained from apple. The 10,16-dihydroxyhexadecanoic acid predominated, to the extent of 45 per cent of the cutin acids.

Examination of the cutin of different plants. The isolated 9,10,18-trihydroxyoctadecanoic and 10,16-dihydroxyhexadecanoic acids and samples of 10,18-dihydroxy- and 18-hydroxyoctadecanoic acids obtained elsewhere were used as reference compounds in the identification and assessment of the ether-soluble acids in the cutin of different plants. Reversed phase chromatography using castor oil-impregnated paper and 60 per cent acetic acid as the mobile phase[21] was used, and the acids were detected with lead acetate and sodium rhodizonate[22]. R_F values at 25° C were as follows: 9,10,18-trihydroxyoctadecanoic acid 0·64, 10,16-dihydroxyhexadecanoic acid 0·52, 10,18-dihydroxyoctadecanoic acid 0·33, and 18-hydroxyoctadecanoic acid 0·02.

Waxes were removed from disks of leaves (about 1,000 cm² surface area) or of fruits (about 100 cm²) by extraction with chloroform, and the cuticular membranes were isolated by ammonium oxalate–oxalic acid treatment. Attached cellulosic remnants were removed with zinc chloride–hydrochloric acid, and the membranes were refluxed with successive portions of 1 per cent potassium carbonate solution until the extract was no longer coloured. The membranes were washed with water and alcohol and dried, treated with 3 per cent ethanolic potassium hydroxide at room temperature, and the liberated ether-soluble acids isolated. The acids were applied to the paper in solution in methanol (up to 50 μg/5 μl.). The occurrence and relative proportions of the cutin acids assessed from comparisons with standards are shown in Table 1.

Table 1. Ether-soluble Cutin Acids in the Cutin of Plants

	9,10,18-trihydroxy-octadecanoic acid	10,16-dihydroxy-hexadecanoic acid	10,18-dihydroxy-octadecanoic acid	18-hydroxy-octadecanoic acid

Apple (Dove)	+ + +	+ + +		+
Apple (Dabinett)	+ + +	+ + +	+	+

Earlier work[4,16] has shown that purified cutin yields about 80 per cent of ether-soluble acids. Indications were obtained of the presence, among the ether-soluble acids from *Euonymus*, potato, apple and pear cutins of small amounts of an unsaturated acid of R_F 0·10. The 10,16-dihydroxyhexadecanoic and 9,10,18-trihydroxyoctadecanoic acids clearly were major components of the cutin of the plants examined.

The results shown in Table 1 provide interesting comparisons. The cutin of the apple and pear, of the botanical sub-family Pomoideae, yielded approximately the same proportions of the four acids, with 9,10,18-trihydroxyoctadecanoic and 10,16-dihydroxyhexadecanoic predominating, while that of the gooseberry and blackcurrant, of the Ribesioideae, gave largely 10,16-dihydroxyhexadecanoic acid. Eglinton *et al.*[23] have shown that the composition of the paraffin fraction of the cuticular wax is characteristic of a species and may be useful for taxonomic purposes. It may be that cutin composition also follows botanical classification.

We thank Dr. M. Matic of the Transvaal and Orange Free State Chamber of Mines, Johannesburg, also Prof. E. Stenhagen, Institute for Medical Biochemistry, Gothenburg, Sweden, and Prof. I. Ribas, University of Santiago de Compostela, Spain, who supplied samples of hydroxy-fatty acids. We also thank Miss M. F. Roberts for the histological work demonstrated in Fig. 1 and Mr. D. R. Clifford for the elemental and infra-red analyses.

EFFECT OF GIBBERELLIN ON VARIETAL IDENTITY IN RED CLOVER (*TRIFOLIUM PRATENSE* L.)

By Dr. J. L. STODDART
Welsh Plant Breeding Station, Aberystwyth

In earlier investigations of the effect of gibberellin A_3 applied to late-flowering genotypes of red clover, pronounced changes in rate of tillering, stem extension and leaf shape were noted[1]. It became evident that gibberellin could modify many of the morphological characters which are commonly used to distinguish between early- and late-flowering varieties of red clover so that the overall result of gibberellin treatment of a late-flowering genotype was the production of a plant which in most respects phenotypically resembled an early-flowering variety. Interest was centred, therefore, on the effect of similar treatment on early-flowering genotypes.

Clonal propagants of Dorset Marl (an early-flowering variety) and Aberystwyth *S*.123 (late-flowering) were established in vermiculite, under a 10-h day-length, at 15·5° C for one month in order to produce vigorous vegetative growth. After this pre-treatment the plants were placed in a growth chamber which provided an inductive day-length of 16 h at 18° C. A completely randomized layout was adopted. Half the propagants of each variety received gibberellin A_3 (500 μg/plant/application) at the first and sixth internode stages and the remaining plants were sprayed with solvent only (0·1 per cent ethanol).

All plants showed significant responses to gibberellin in terms of stem elongation, tillering, leaf shape and general growth habit, but the response was considerably greater in the late-flowering variety. Comparison of leaves produced at a given stem internode in the two varieties showed that the characteristic difference in length/breadth could not be detected in the presence of gibberellin. Similarly, the profuse basal vegetative tillering characteristic of late-flowering varieties was completely inhibited by the first gibberellin treatment, giving rise to an open crown habit typical of early-flowering types. The close similarity in appearance between untreated Dorset Marl and treated *S*.123 is clearly shown in Fig. 1, and at this growth stage using normal diagnostic methods it was not possible to distinguish between the varieties.

At flowering certain varietal characteristics persist, notably the greater number of extended stem internodes produced before terminal inflorescence emergence in *S*.123 and the earlier date of flowering in Dorset Marl, but the time difference is considerably reduced by gibberellin treatment.

Fig. 1. Response of early and late-flowering red clovers to gibberellin A_3. Top, *S*.123 and Dorset Marl (control);—bottom left, Dorset Marl (control); bottom right, *S*.123 treated with gibberellin

perfusion of distilled water, Ringer's solution, and 1 per cent glucose-Ringer's solution. In normal subjects absorption of sodium, chloride and potassium occurred proximally and secretion distally when Ringer's solution was perfused. This proximal-distal relationship was reversed in a patient with non-tropical sprue, in accord with greater intensity of damage to the mucosa in the proximal small gut.

Substitution of 1 per cent glucose in equimolar proportions for sodium and chloride greatly augmented absorption rates of normal subjects, especially in the proximal small gut, where glucose absorption is greatest. The 4–100-fold increase in sodium absorption occurred despite a gradient for sodium secretion. Glucose also caused sodium absorption to occur in the distal small gut, where secretion occurred with Ringer's.

In a patient with non-tropical sprue, the proximal-distal net transfer relationships of the small intestine for 1 per cent glucose-Ringer's were the reverse of normal. Absorption of glucose and electrolytes in the distal small gut in sprue was as high as in the proximal small gut of normals. Thus, in sprue the distal small gut has adapted to the damage and loss of absorbing capacity in the proximal small gut. The distal has in part taken over the proximal small gut functions.

Glucose, sodium and chloride tend to be transported in equimolar proportions across all regions of the small intestine in normal subjects, and the distal in sprue. This is the first demonstration of such a linkage in transport under physiological conditions in man.

X-RAY INHIBITION OF URETHAN-STIMULATED PROLIFERATION OF LUNG CELLS OF THE MOUSE AS ESTIMATED BY INCORPORATION OF TRITIATED THYMIDINE

By WILLIAM A. FOLEY*, LEONARD J. COLE, BERYL J. INGRAM and T. TIMOTHY CROCKER†

Biological and Medical Sciences Division, U.S. Naval Radiological Defense Laboratory, San Francisco, and Department of Medicine and Cancer Research Institute, University of California Medical Center, San Francisco

IN an effort to extend our recent observation that 880 rads of whole-body X-irradiation inhibits the well-known induction of pulmonary tumours by urethan in mice[1], we have investigated the uptake of tritiated thymidine by cells of the mouse lung during the first 10 days following a single injection of urethan and/or total body X-irradiation. The purpose was to determine whether increased cell proliferation induced by urethan[2,3] was altered by tumour-inhibiting doses of X-rays. Previous reports[1,4,5] have emphasized the paucity of discrete pulmonary histopathological changes following urethan injection during the first several weeks, while Shimkin and Polissar[2] found a progressive increase in cellularity during this early period.

Twenty 5-week-old $(C57L \times A)F_1$ male mice were given 0·2 ml. of a 10 per cent solution of urethan intraperitoneally. This dose alone is sufficient to cause multiple pulmonary tumours in every animal[1]. Twenty-four hours later, 10 of the urethan-treated mice plus an additional group of 10 normal mice were exposed to 880 rads of whole body X-irradiation (250 kVp.; 15 m.amp; filter 0·5 mm copper plus 1·0 mm aluminium; half-value layer 1·28 mm copper; 100 cm target to skin distance; dose rate, 30 rads/min). This radiation dose is approximately 100 rads higher than the LD_{99} and is the same dose we used previously[1]; bone marrow cells to afford protection against radiation death were not injected in this work. Non-irradiated, untreated mice served as controls.

Tritiated thymidine (specific activity 1·9 c/m.mole) was diluted with physiological saline to give a concentration of 100 μc./ml. and 0·2 ml. of this solution was given intraperitoneally to each animal at 6 h and at 3 h before killing. Mice were killed at the same time each day by cervical dislocation, the lungs were fixed whole, cut transversely into multiple blocks for routine dehydration and paraffin embedding, and sectioned at 5μ. After Feulgen hydrolysis and staining, sections were covered with Kodak '*AR*-10' stripping film and exposed for 7 weeks. Unstained sections gave the same proportion of labelled cells as sections subjected to the hydrolysis of the Feulgen method.

Labelled cells were counted in sub-pleural and deeper fields over alveolar zones only, using an ocular grid. Sections of lung from control and experimental animals were alike in cellularity in these experiments and the ocular grid enclosed an average of 68 nuclei. The number of labelled cells per 100 grid areas was recorded (Table 1) after at least 150 grids had been counted for each animal. Labelled cells were not localized in sub-pleural or deep alveolar zones, and no discrete histological differences were noted between treated and control mice.

Table 1. EFFECT OF URETHAN AND X-IRRADIATION ON PROLIFERATION OF LUNG CELLS OF THE MOUSE AS ESTIMATED BY UPTAKE OF TRITIATED THYMIDINE

Time after treatment (days)	No. of labelled cells per 100 grid fields: Urethan only	Urethan 24 h before X-rays	X-rays only	No treatment (normal controls)
1	8·9	1·2	1·0	26·4
2	27·0	1·3	0·6	—
4	86·0	3·3	22·0	—
7	94·0	12·0	34·6	—
10	259·0*	—	—	33·0*

Five week-old male LAF_1 mice (14–17 g). Figures represent averages of two animals, except where indicated, in which case only one animal was counted.
Urethan—0·2 ml. of 10 per cent solution intraperitoneally.
X-rays 880 rads whole-body exposure; 250 kVp., 15 m.amp.

In 3 control animals (Table 1, last column) there was an average of about 30 labelled cells per 100 grid areas. At 68 cells per grid area, this represents a labelling rate of 0·44 per cent, which is lower than the rate obtained by Schultze and Oehlert[6] although it is in the range of values for growing cell populations reported by Leblond *et al.*[7].

Urethan decreased the proportion of nuclei labelled on the first day after injection, but the proportion of labelled nuclei rose in one week to three times the control value (Table 1, column 2). The very high proportion of labelled nuclei at 10 days occurred in the only animal available; it may indicate a more extensive effect than suspected at present and would require future evaluation.

The rising proportion of labelled nuclei in the alveolar zone of the lungs of the urethan group agrees with the 3-fold increase in labelling and mitotic rate found 13 days

* Present address: Department of Pathology, University of Minnesota.
† Supported in part by the American Cancer Society, California Division.

after urethan by Crocker and Hill[3] and with the rapid increase in general cellularity of the lung reported by Shimkin and Polissar[2].

The initial decline in proportion of labelled nuclei one day after urethan suggests a brief inhibition of cell multiplication. The mechanism for such an effect is not known, but might be similar to suppression of cell multiplication demonstrated in other investigations[8,9]. Rogers's observations[10] that injections of DNA or of various nucleic acid precursors antagonize pulmonary tumour induction by urethan suggest that urethan interferes with DNA metabolism. The evidence that ultra-violet radiation at a wave-length of maximal DNA absorption will produce pulmonary tumours similar to those obtained with urethan[11], and the fact that urethan is known to elicit chromosome abnormalities in cells of many species[9], suggest that the induction of pulmonary tumours by urethan involves events at chromosomal or sub-chromosomal levels.

X-irradiation alone sharply reduced the proportion of labelled nuclei during days 1 and 2, but the labelling rates had returned to control values by day 7 (Table 1, column 4). The effect of urethan followed in 24 hours by X-irradiation (880 rads) was a marked and persistent reduction in the proportion of cells in DNA synthesis (Table 1, column 3). This effect was greater and lasted longer than the suppression of cell replication produced by X-irradiation alone, suggesting that urethan increased the radiosensitivity of pulmonary cells.

Inhibition of cell multiplication by X-rays is well known, but the mechanism is only partially understood. X-irradiation inhibits thymidine kinase and DNA polymerase activity in rat liver following partial hepatectomy[12], and in the kidney following unilateral nephrectomy[13]. Both these biological systems are in a state of cellular proliferation aimed at replacing a functional mass of tissue. The corresponding finding here is that X-irradiation (880 rads) suppressed urethan-induced cellular proliferation.

In previous longer-term experiments, exposure to 880 rads of whole-body X-irradiation 3 h before giving urethan, or at 3 h or 24 h after giving urethan eliminated the lung tumour-promoting property of urethan while X-irradiation as late as 7 days after giving urethan reduced tumour incidence markedly[1]. The results presented here demonstrate that the same X-irradiation dose which eliminated tumour emergence suppresses the early widespread rapid cell proliferation characteristic of the early response to urethan.

CUTIN OF PLANT CUTICLES

By E. A. BAKER and Dr J. T. MARTIN
Long Ashton Research Station, University of Bristol

THE structure of the cuticle, or surface skin, of the higher plants has been established during the past century by anatomical and chemical work which has recently been reviewed[1,2]. The cuticle assumes the form of a non-cellular membrane covering the cellular tissue. The chief structural component of the membrane is cutin; this occurs throughout the membrane, but becomes diluted with pectin (and cellulose) as the membrane merges into the outer walls of the epidermal cells (Fig. 1). Waxes embedded in the membrane and extruded from its surface give plants their water-repellent properties. The cuticular membrane has been likened to a sponge with capacity to absorb water and swell. In the apple leaf, the cutin is deposited as lamellæ parallel to the surface with pathways through the membrane facilitating the passage of water-soluble substances[3]. Wide variations have been found in the levels of cutin in the cuticles of different plants[4,5] and in those of leaves and fruits of one species; the mature apple fruit, for example, carries ten times more cutin per unit area of surface than the fully formed leaf[6]. The cuticle contributes much to the well-being of the plant; it protects the cellular tissues, absorbs ultra-violet light, conserves water and nutrients, and participates in respiration. Interest in the plant cuticle has been stimulated in recent years by the recognition of its influence on the behaviour and efficiency of crop protection chemicals and of the part it may play in providing a mechanical barrier to the invasion of plants by fungi[1,2,7,8]. Heinen[9] has made the interesting observation that cutin is broken down by 'cutinase' produced by a leaf-rotting fungus.

Chemical nature of cutin. By contrast with the cuticular waxes, the identities of which are now well known, little information is available on the chemistry of cutin. Up to 1885, Fremy[10] obtained two acids, stereocutic and oleocutic, from the cutin of apple, ivy and a species of *Agave*. Lee[11] in 1925 concluded from work on flower petals and rhubarb petioles that cutin was a complex mixture of fatty acids, free and combined with alcohols, that had undergone condensation and oxidation. This supported the view of Lee and Priestley[12] that the cuticle was formed from lipoidal substances, formed or mobilized in the epidermis, that migrated to the surface and oxidized to give a 'varnish-like' covering. Legg and Wheeler[13] saponified the cutin of leaves of *Agave americana* and *A. rigida* and isolated cutic and cutinic acids; cutic acid comprised 65 per cent of the acids obtained. Markley and Sando[14] considered that cutin was an ester-like substance yielding fatty acids on hydrolysis, and Roelofsen and Houwink[15] referred to cutin as "a polymolecular network of several dicarboxylic and hydroxycarboxylic acids connected through ester and ether bridges".

More recently Huelin[16] has suggested that cutin, a polyester of hydroxylated acids and other substances, is probably formed under the control of a specific and localized enzyme. An important step forward was made in 1956 by Matic[17], who isolated 9,10,18-trihydroxyoctadecanoic, 10,18-dihydroxyoctadecanoic, 18-hydroxyoctadecanoic, 18-hydroxyoctadec-*cis*-9-enoic and 10,16-dihydroxyhexadecanoic acids also from the leaf cutin of *A. americana*. The first-named predominated, and the five acids accounted for more than 80 per cent of the ether-soluble acids liberated from the cutin. The 9,10,18-trihydroxyoctadecanoic and 10,16-dihydroxyhexadecanoic acids have also been isolated[18] from olive leaves; they were

Assays of endogenous gibberellin-like activity were performed on extracts from Dorset Marl and *S.*123 made at different growth stages during early stem extension. The extraction was carried out on 500 g fresh weight samples with 1 : 1 acetone/water for 20 h at 0° C after which the extract was reduced to the aqueous fraction by *in vacuo* distillation. The gibberellin-like activity was adsorbed on activated charcoal at *p*H 3 and eluted with acetone, the final eluate being concentrated for chromatography by rotary film evaporation.

Each extract was loaded on to strips of Whatman 3 mm paper and chromatographed in a descending solvent system of 80 per cent isopropanol. Chromatogram sections were eluted and assayed for activity using the d1 dwarf maize assay[2]. It was generally possible to detect two active zones on each chromatogram, one at R_F 0·3–0·4 and the other at R_F 0·6–0·7 which varied according to growth stage (Table 1)

The possible functions of the activity in the two zones have been discussed in an earlier publication[3], and it was concluded that both play a part in stem extension although the R_F 0·6–0·7 activity also appears to have some correlation with floral initiation. In terms of total activity it is evident that at any given stage during early stem extension less gibberellin is present in the late-flowering type, which fits the observation that the rate of stem extension is initially slower in late varieties. The results suggest that the effects of applied gibberellin on a late-flowering variety result from the supplementation of a system in which gibberellin is limiting, whereas the lesser response of early-flowering types could be due to the presence of a near-optimal gibberellin-level at an early growth stage.

Table 1. GIBBERELLIN-LIKE ACTIVITY IN EARLY- AND LATE-FLOWERING RED CLOVER

Variety	No. of internodes	GA_3 μg equiv./kg fresh weight R_F 0·3–0·4	R_F 0·6–0·7	Total
Dorset Marl	1	0·40	0·36	0·76
*S.*123	1	0·12	0·00*	0·12
Dorset Marl	2	0·30	0·41	0·71
*S.*123	2	0·20	0·12	0·32
Dorset Marl	3	0·26	0·56	0·82
*S.*123	3	0·22	0·15	0·37
Dorset Marl	4	1·50	0·78	2·28
*S.*123	4	0·25	0·33	0·58

* No significant response in bioassay.

The participation of gibberellins in the expression of genetic differences has been reported previously in dwarfed genotypes of *Pisum sativum*[4], *Zea mays*[2] and *Lolium perenne*[5]. In each instance it was demonstrated that dwarfism due to single gene differences could be overcome by spraying with gibberellic acid, phenotypically normal plants being produced.

Although the aggregate morphological difference between early and late red clovers clearly has a polygenic basis, it is evident from the foregoing data that the morphogenesis of some of the individual characters can be described in terms of differences in gibberellin content.

A simple scheme to explain the effects of exogenous gibberellin and also to account for the more rapid response to inductive day-length in Dorset Marl would be one which suggested that the rate of inception of gibberellin synthesis in response to long-days was more rapid in the early-flowering type.

CONVERSION OF DOPAMINE TO 3,4-DIMETHOXYPHENYLACETIC ACID IN SCHIZOPHRENIC PATIENTS

By PROF. ARNOLD J. FRIEDHOFF and ELNORA VAN WINKLE
Research Unit, Department of Psychiatry and Neurology, New York University School of Medicine

IN a previous investigation, in this laboratory, a biologically active compound, 3,4-dimethoxyphenylethylamine, was identified in the urine of schizophrenic patients[1,2], and it was suggested that this compound might be formed from 3,4-dihydroxyphenylethylamine (dopamine). The present investigation was initiated in order to determine whether 3,4-*O*-methylation of dopamine occurs.

Five hospitalized patients with a confirmed diagnosis of schizophrenia were selected. 3,4-Dimethoxyphenylethylamine had been identified previously in the urine of each of these patients. 3,4-Dihydroxyphenylethylamine-7^{3}H.HCl (specific activity 24·0 mc./m.mole) was dissolved in 200 c.c. of normal saline and approximately 200 μc. of this compound were administered to each patient by intravenous infusion. Urine was collected for a period of 3 h. The urine from each of 3 patients was analysed separately while the extracts of the urines of 2 other patients were pooled in order to increase the concentration of radioactivity.

The urine was extracted by a method previously described[1,2]. In brief, following the infusion, the urine was extracted with chloroform at *p*H 2. The aqueous phase was adjusted to *p*H 9 and again extracted with chloroform. The material extracted at *p*H 9 was co-chromatographed in butanol : formic acid : water (12 : 1 : 6) with 3,4-dimethoxyphenylethylamine and 4-hydroxy-3-methoxyphenylethylamine. Control strips were cut and dipped in ninhydrin-pyridine reagent in order to locate the reference compounds. The chromatograms were scanned in a Tracerlab 4 π chromatogram scanner, and a peak was found that corresponded to 4-hydroxy-3-methoxyphenylethylamine on each chromatogram. A second peak corresponding to 3,4-dimethoxyphenylethylamine was identified on each chromatogram. However, this peak did not represent sufficient activity for further analysis by isotope dilution methods. The radioactivity corresponding to 3,4-dimethoxyphenylethylamine is at present being analysed by other techniques.

The organic phase from the *p*H 2 extraction contained the acidic and neutral metabolites. This extract was evaporated to a small volume and applied for chromatography. The chromatogram was developed in butanol : acetic acid : water (4 : 1 : 1). The chromatograms were scanned for radioactivity. Control strips were cut from the chromatograms of this fraction and were dipped in aniline-xylose reagent[3]. One broad radioactive area with its peak at R_F 0·81 was found. It corresponded to the areas of both 4-hydroxy-3-methoxyphenylacetic acid and 3,4-dimethoxyphenylacetic acid. The material in this area was eluted by wetting the chromatographic paper with 0·01 N hydrochloric acid and extracting it with chloroform. The chloroform was evaporated and the residue was applied for chromatography. The chromatogram was developed in ethanol : concentrated ammonium hydroxide : water (16 : 1 : 3). In each case a scan of the developed chromatogram revealed a radioactive peak at the R_F of co-chromatographed 4-hydroxy-3-methoxyphenylacetic acid (R_F 0·58). A second peak was found that corresponded to 3,4-dimethoxyphenylacetic acid

(R_F 0·69). The urine obtained from patient No. 5 was first extracted at *p*H 9 and then at *p*H 2 to eliminate neutral metabolites from the *p*H 2 extract. The resulting scan of the chromatogram of the acid extract from this patient also displayed the two peaks already described.

An area, 5 mm wide, was cut across the portion of each chromatogram corresponding to the 3,4-dimethoxyphenylacetic acid reference. This area of the paper was wetted with 0·01 N hydrochloric acid and the radioactive material was eluted with chloroform. The chloroform was evaporated and the material was recrystallized from 0·1 N hydrochloric acid with authentic 3,4-dimethoxyphenylacetic acid as the carrier. In addition, radioactive material corresponding to 4-hydroxy-3-methoxyphenylacetic acid was eluted and was also recrystallized with authentic 3,4-dimethoxyphenylacetic acid. The radioactivity of the samples was assayed by means of a Tracerlab gas-flow proportional counter and a Packard Tri-Carb liquid scintillation counter.

The results of the carrier analyses are summarized in Table 1. It will be noted that the activity corresponding to 3,4-dimethoxyphenylacetic acid maintained constant specific activity. This constitutes presumptive evidence that the radioactive material is 3,4-dimethoxyphenylacetic acid. The 4-hydroxy-3-methoxyphenylacetic acid was not carried through 3 recrystallizations with 3,4-dimethoxyphenylacetic acid as the carrier.

Table 1. Results of Carrier Analyses

Radioactive material corresponding to 3,4-dimethoxyphenylacetic acid recrystallized with 3,4-dimethoxyphenylacetic acid as carrier	Specific activity c.p.m./mg*			
	No. recrystallizations			
	1	2	3	4
Patient No.				
1	23·9	24·4	21·0	
2	17·5	16·3	22·1	
3 and 4 (pooled)	75·0	77·0	82·7	68·0
5	24·4	26·9		
Radioactive material corresponding to 4-hydroxy-3-methoxyphenylacetic acid recrystallized with 3,4-dimethoxyphenylacetic acid as carrier				
Patient No.				
1	28·2	13·8	10·4	
2	11·8	8·4	6·6	

* The standard error of the group mean is based on the use of the 'within group variance'. Using paired replicate samples the standard error of the mean of the specific activities of all the samples is ± 0·52.

To obtain further evidence for the metabolic conversion of dopamine to 3,4-dimethoxyphenylacetic acid a liver biopsy was performed on patient No. 5. The liver obtained (0·1 g wet weight) was homogenized with 10 c.c. of 0·5 N phosphate buffer *p*H 7·9. The whole homogenate was incubated at 37° C for 2 h with 0·1 c.c. 0·5 M magnesium chloride, 0·60 μmoles 3,4-dihydroxyphenylethylamine-7^{3}H.HCl and 0·96 μmoles of *S*-adenosyl-L-methionine methyl-^{14}C. The specific activities of dopamine and *S*-adenosyl-L-methionine were 24·0 mc./m.mole and 26·1 mc./m.mole, respectively. After incubation the sample was deproteinized with 15 c.c. of 5 per cent *m*-phosphoric acid and centrifuged. The supernatant fluid was decanted and adjusted to *p*H 2 with concentrated hydrochloric acid and extracted with chloroform. The chloroform was dried with anhydrous sodium sulphate and was then evaporated to a small volume. 3,4-Dimethoxyphenylacetic acid and 4-hydroxy-3-methoxyphenylacetic acid were added to the concentrated extract which was then applied for chromatography. The chromatogram was developed in ethanol: concentrated ammonium hydroxide: water (16 : 1 : 3). A control strip was dipped in aniline-xylose reagent. The chromatogram of the acid metabolites was scanned for radioactivity and, as can be seen in Fig. 1, peaks corresponding to reference 4-hydroxy-3-methoxyphenylacetic acid (peak I) and 3,4-dimethoxyphenylacetic acid (peak II) were observed. The other regions of radioactivity have not been identified but may be methylated derivatives of compounds other than dopamine. The region of the chromatographic strip corresponding to peak I and that corresponding to peak II were eluted separately with ethanol. The radioactivity was assayed in a Tri-Carb liquid scintillation counter.

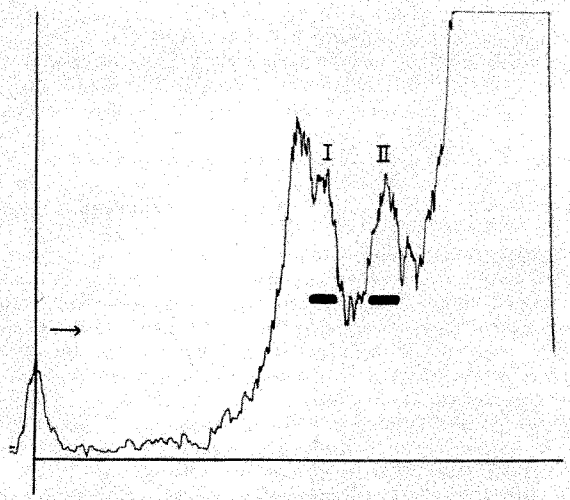

Fig. 1. Scan of a radiochromatogram developed from an extract obtained from the incubation of dopamine-7^{3}H, *S*-adenosyl-L-methionine-methyl-^{14}C and liver from a schizophrenic patient

Each mole of dopamine-7^{3}H will accept one methyl carbon-14 group for each mole of 4-hydroxy-3-methoxyphenylacetic acid formed and 2 methyl carbon-14 groups for each mole of 3,4-dimethoxyphenylacetic acid formed. The theoretical value for the ratio

$$\frac{\text{d.p.m. } ^{14}\text{C} \div \text{specific activity } ^{14}\text{C}}{\text{d.p.m. } ^{3}\text{H} \div \text{specific activity } ^{3}\text{H}}$$

would be 1 for the hydroxymethoxy compound and 2 for the dimethoxy compound. The ratio for the sample eluted from the area of 4-hydroxy-3-methoxyphenylacetic acid (peak I) was found to be: $\frac{1605 \div 26{\cdot}1}{1601 \div 24{\cdot}0} = 0{\cdot}921$.

The ratio for the sample eluted from the area of the 3,4-dimethoxyphenylacetic acid was $\frac{1583 \div 26{\cdot}1}{747{\cdot}7 \div 24{\cdot}0} = 1{\cdot}95$.

These results indicate that 3,4-dimethoxy as well as the usual 4-hydroxy-3-methoxy metabolites of dopamine are synthesized by schizophrenic patients. However, since biological samples from schizophrenic patients, but not from normal controls, were used in this investigation, a relationship between 3,4-dimethoxyphenylacetic acid and schizophrenia has not been demonstrated.

In this work it has been shown that dopamine can be converted enzymatically to a dimethoxy derivative both *in vivo* and in a homogenate made from liver tissue obtained from a schizophrenic patient. It has been shown previously that 3,4-dimethoxyphenylethylamine is readily converted to its corresponding acid derivative by monoamine oxidase[4]. This probably accounts for the large amount of dimethoxy acid excreted as compared with dimethoxy amine. From these results it seems likely that only a small part of the 3,4-dimethoxyphenylethylamine of endogenous origin is excreted unmetabolized, while a large portion of this compound is probably excreted as 3,4-dimethoxyphenylacetic acid.

This work was supported in part by grants from the National Institute of Mental Health, U.S. Public Health Service and the Schweppe Foundation.

RADIO ASTRONOMY

Radiation from Jupiter at 178 Mc/s

A NUMBER of observations have been made of the decimeter radio emission from Jupiter at frequencies between 3 cm and 70 cm.

Although there is some evidence that the emission at a given frequency shows some variation with time, the results, when corrected to the same distance for the planet, provide a fairly well defined spectral law (see, for example, the review article by Roberts[1]).

The origin of the emission has been attributed to radiation by relativistic electrons trapped in the Jovian magnetic field in a manner analogous to the terrestrial Van Allen belt[2]. If this interpretation is correct a more accurate determination of the spectral distribution of the non-thermal component, especially at the lower frequencies, is of considerable interest in connexion with the energy spectrum of the trapped particles.

Observations at a frequency of 178 Mc/s have, therefore, been made at the Mullard Radio Astronomy Observatory using the large east–west interferometer[3]. At a frequency as low as this, the expected flux density is small and there is some difficulty in distinguishing between the radiation from Jupiter and the radiation from the numerous radio sources having a comparable flux density. Consequently, it is necessary to develop an observing procedure whereby the records obtained on one day are subtracted from those taken on another day when the position of Jupiter has altered by more than the beam width of the instrument; in this way it becomes possible to detect a source very much weaker than could normally be distinguished if there were no relative motion.

Observations were made both with a fan-beam system and with an interferometer having a separation of 469λ between its elements; a comparison of the two records then enables limits to be set on the angular diameter of the source[4]. The observations were made over the period June 22–July 1, 1963, and the method of subtracting the records was used on both fan beam and interferometric systems to provide a series of ten independent determinations of the apparent flux density of Jupiter on each system.

The mean values derived were:

(*a*) Flux density using fan beam, $3{\cdot}3 \pm 0{\cdot}45 \times 10^{-26}$ W m^{-2}(c/s)$^{-1}$

(*b*) Flux density on interferometer, $3{\cdot}8 \pm 0{\cdot}4 \times 10^{-26}$ W m^{-2}(c/s)$^{-1}$

The day-to-day variations in the measured flux density were close to the values expected from the combined effects of noise and small variations in the phase of the interference pattern caused by ionospheric irregularities; these phase variations lead to a small residual component when subtracting the records from different days.

It can therefore be concluded that over the period of observation the flux density of Jupiter did not vary by more than 20 per cent. Furthermore, since, over this period, the day-to-day variations in electron content of the ionosphere are sufficient to cause variations in the Faraday rotation of more than 45°, the results indicate that at 178 Mc/s any polarized component of the emission is less than 20 per cent.

A comparison of the fan beam and interferometric observations allows an upper limit of 1·5 min arc to be set to the source diameter, on the assumption of a Gaussian strip distribution. With a circular source of this angular diameter the surface brightness would correspond to a brightness temperature $T_s > 1{\cdot}7 \times 10^4$ °K; if the source were the same size as the optical disk $T_s = 8{\cdot}6 \times 10^4$ °K.

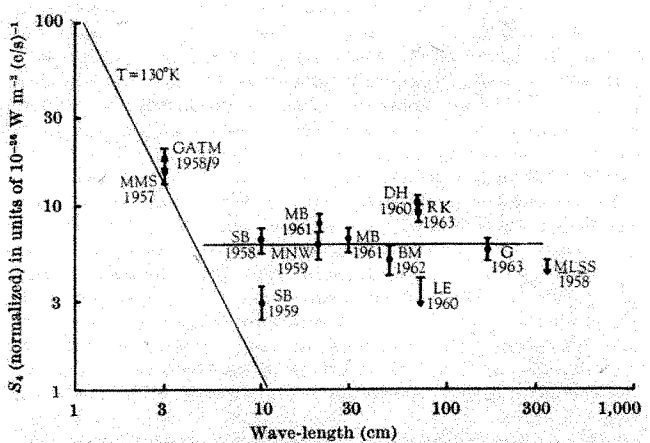

Fig. 1. Flux density of Jupiter corrected to a standard distance of 4·04 A.U. *GATM* 1958/59, see ref. 5; *MMS* 1958, ref. 6; *SB* 1958 and *SB* 1959, ref. 7; *MB* 1961, ref. 8; *MNW* 1959, ref. 9; *BM* 1962, ref. 10; *RK* 1963, ref. 11; *DH* 1960, ref. 12; *LE* 1960, ref. 13; *MLSS* 1958, ref. 14. '*G*1963' refers to the present observations.

The flux densities derived from these and a number of other observations have been corrected to a distance to the planet of 4·04 A.U. and are shown in Fig. 1.

The observed spectrum has been fitted in the figure by the adoption of a thermal contribution corresponding to a temperature of 130° K, as suggested by Roberts[1], and of a non-thermal component which has a spectral index, α, of 0, and for which S equals 6×10^{-26} W m^{-2} (c/s)$^{-1}$.

Although the points show considerable scatter, part of which may be due to temporal variation in the source, the new observations suggest that the spectral index is less than the figure of 0·3 given by Roberts[1].

I would like to thank Dr. P. F. Scott for assistance with the observations.

GEOPHYSICS

Magnetotelluric and Very Low Frequency Signatures from Small High-Altitude Nuclear Explosions

THIS communication presents a preliminary account of the magnetotelluric and very low frequency signatures associated with the U.S. high-altitude nuclear detonations of October 20 (0830 : 00 G.M.T.), October 26 (0959 : 49 G.M.T.), November 1 (1210 : 06 G.M.T.), and November 4

(0730 : 00 G.M.T.) 1962, observed at our field station near Rochester, New York. Three orthogonal components of dB/dt in the band 0·001 to 3 c/s were sensed with cored loop antennæ of sensitivity 0·07 mV-sec/γ. A pair of electrodes spaced 225 ft. apart sensed the north–south component of the telluric-current field in the same band. A whistler-recording apparatus furnished a broadband very low frequency noise record.

In contrast to the test of July 9, 1962, the four October–November tests displayed generally weak and variable signatures at our station. The magnetotelluric records consisted of the usual continuum background plus a series of short oscillatory transients 0·5–1 sec long. The broadband VLF noise record enabled us to exclude magnetotelluric transients arising from the 'slow tails' of lightning discharge waveforms. A sonagram analysis of this record was scanned for all strong spherics with large amounts of ELF (10–1,000 c/s) energy, and any magnetotelluric transients coincident in time with these spherics were rejected as arising from natural atmospheric effects. The remaining features were assumed to originate with the nuclear detonation, and were classified as either 'prompt' (essentially simultaneous with the instant of detonation) or 'delayed'.

Fig. 1 gives a scheme of the magnetotelluric results from the two low-yield devices detonated on October 20 and November 4. The essential observations are the following: (1) a large prompt magnetotelluric pulse occurred in all channels on October 20; there was no discernible prompt magnetotelluric pulse on November 4; (2) following detonation on October 20 almost two complete cycles of 0·3 c/s signal, with peak-to-peak amplitude of 0·05 γ, appeared in the north–south and east–west magnetic channels; similar frequencies were observed during the first half-minute following the July 9 detonation[1]; (3) delayed pulses appeared at $H+4{\cdot}7$ sec on October 20 and $H+6{\cdot}5$ sec on November 4, in both north–south and vertical magnetic channels; (4) a prompt broadband VLF pulse was observed on October 20.

Fig. 2 shows magnetotelluric results from the sub-megaton-yield tests of October 26 and November 1. The

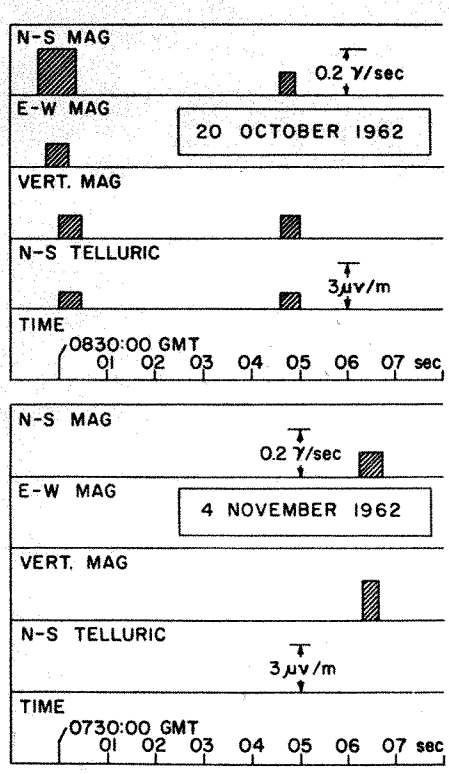

Fig. 1. Magnetotelluric summary diagrams, October 20 and November 4, 1962 tests

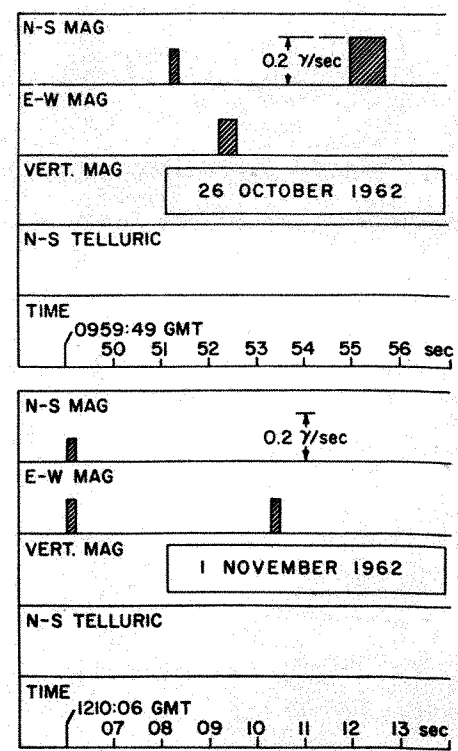

Fig. 2. Magnetotelluric summary diagrams, October 26 and November 1, 1962 tests

data show that: (1) on November 1 a prompt pulse occurred in the north-south and east-west magnetic channels, simultaneous with a prompt broadband VLF pulse, with most of the energy in the latter concentrated above 5 kc/s; (2) no prompt magnetotelluric pulses appeared on October 26; there were, however, two north–south magnetic pulses delayed by 2·5 and 6 sec, respectively; (3) the only delayed pulse on November 1 was a relatively weak east–west magnetic signature at $H+4{\cdot}5$ sec. The large natural background present on November 1 could, however, have obscured other effects.

During the last three tests of the series, we measured phase delays (for a 20-sec period following detonation) on the 18·6-kc/sec signal transmitted from station *NPG* near Seattle, Washington. On November 1, a rapid-onset phase decrease of the neutron-decay type[2,3], with an initial slope of 30°/min, was observed. On November 4 the rapid-onset phase decrease did not exceed 15°/min in the 20-sec observation period. Rapid-onset results on October 26 were inconclusive. However, an interesting coincidence of transient phase excursions was noted; in all three tests observed, the *NPG* signal displayed a rapid, transient phase excursion of 7°–10° peaked at $H+13$, $H+12$, and $H+11$ sec respectively. The probability of chance coincidence is less than 1 in 10. We therefore conclude that the evidence of delayed transient phase excursions is suggestive but scarcely conclusive.

Results of the four tests may be summarized as follows: (1) the prompt magnetotelluric signatures were highly variable; (2) on October 26 a delayed magnetotelluric signature occurred 2·5 sec after detonation; (3) a magnetotelluric signature component delayed by 4–7 sec occurred consistently for all four tests; (4) prompt broadband VLF pulses were observed only on October 20 and November 1; (5) besides the well-known neutron-decay phase delays, there was weak evidence of a transient phase excursion on the VLF signal propagated from station *NPG*, occurring about 12 sec after detonation of the last three tests.

The magnetotelluric and phase-transient signatures show average delays of 5 and 12 sec, respectively. If these delays represent the transit time of fast and slow hydro-

magnetic wave modes, the corresponding mode velocities are 1,700 and 450 km/sec. Both these values are about 40 per cent lower than those reported for the Argus tests of 1958[4,5]. In connexion with the 2·5-sec delay observed for one component of the October 26 signature, we point out that Roquet *et al.*[6] have shown that the main phase of the signature from the July 9 test showed a world-wide delay of about 2 sec following the instant of detonation. Reports from other observers on observations of the later American tests may provide further evidence of this important effect. The paucity of published results on the electro-magnetic effects of the October–November 1962 tests, relative to the July 9 test, is due no doubt to the more spectacular nature of the latter. We suggest, however, that attention devoted to the results of the October–November series may prove equally rewarding.

A fuller account of this work is being prepared for publication elsewhere.

Detection of Scattering Layers in the Upper Atmosphere (60–140 km) by Optical Radar

This communication reports observations made by us of optical echoes from atmospheric constituents (presumably dust) at heights of 60–140 km. They were detected with an optical radar. The techniques utilized are a development of those already reported by us[1,2].

The optical radar consists of an RCA-designed ruby laser delivering short pulses of approximately 50 nsec, 0·5 joule at $\lambda = 6{,}940$ Å; of a transmitting refracting telescope of 7·5-cm diameter and 201-cm focal length; of a receiving reflecting telescope of 32-cm diameter and 270-cm focal length, and of a photometer utilizing a 20-Å wide interference filter and a cooled EMI 9,558 *A* photomultiplier. The two telescopes are accurately boresighted and rigidly connected on an equatorial mount. All observations reported here were made with the telescopes looking at the zenith. Each time that the laser was fired the return signals picked up by the photomultiplier were displayed on an oscilloscope and photographed. The return signals originating above 30 km were so weak that it was possible to count individual photoelectrons in each 10-km (66-μsec) interval up to 180 km. These experiments were carried out during the months of June and July 1963 at Lexington, Massachusetts. They show the Rayleigh molecular scattering at heights up to 50–60 km. At greater heights—up to 140 km—very weak echoes were detected which we ascribe to dust clouds. These latter echoes appear to come from two main regions: 60–90 km (often about 80 km) and 110–140 km (often about 120 km).

Fig. 1 shows the results of the observations of four consecutive days, July 28–31. This interval covers the period of the δ-Aquarids meteor shower. The sums of the photoelectrons obtained in successive 10-km range intervals are displayed for each night. The large initial counts, resulting from molecular Rayleigh scattering, permit an independent calibration of the apparatus. The noise-level, which is represented by photomultiplier dark current and sky background, is established by taking the average of the returns in the interval 140–180 km. Independent noise measurements taken between laser firings were in substantial agreement with those taken from the extreme ranges. Since the noise has the character of a Poisson process, the standard deviation is taken to be $\sqrt{n}$, where n is the average noise-level count per range-interval; note that the peaks obtained on July 30 and 31 exceed the average noise-level by more than 3 times the standard deviation.

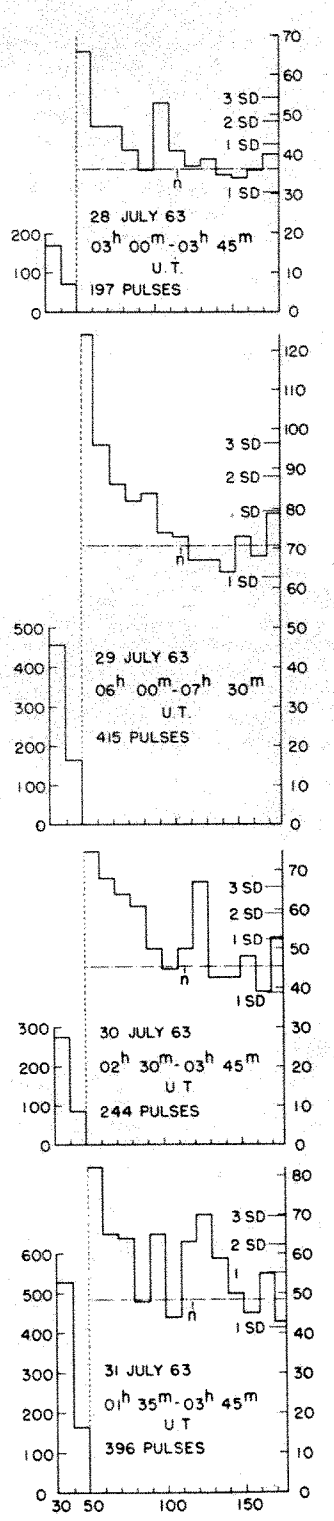

Fig. 1. Accumulated photoelectron counts in 10-km range intervals for July 28–31, 1963; n is the average noise-level

Many similar sets of data have been collected that show similar behaviour. Table 1 was compiled after a pre-

Table 1. Occurrence of Echoes on Nine Nights of Observation

U.T. (1963)	Range (km) 60	70	80	90	100	110	120	130	140
July 17				X		X		X	
July 24		X							
July 25			X	X					
July 26		X							
July 27						X			
July 28									
July 29									
July 30								X	
July 31								X	

liminary analysis of 9 days of observation. The X's show the occurrence of peaks exceeding the average noise-level by a factor of $3\sqrt{n}$. The echoes obtained on July 31 correspond to a backscattering differential cross-section per unit volume (averaged between 120 and 130 km) of $2 \cdot 10^{-13}$ cm^{-1} steradians^{-1}.

In the absence of independent methods of observation we cannot say what causes these echoes. However, one is tempted to compare the lower echoes (~ 80 km) with the observed heights of noctilucent clouds. It has been speculated that more distant echoes (~ 120 km) correspond to the region of meteoric break-up.

The assistance of F. W. Barrows, H. B. Gay, G. A. Garosi, and G. S. Misail in the construction of the apparatus and of H. C. McClees in the conduct of the experiment is gratefully acknowledged. We thank Prof. A. H. Barrett for many helpful discussions. This work was supported in part by the U.S. Army, the Air Force Office of Scientific Research, and the Office of Naval Research; and in part by the National Aeronautics and Space Administration (Grant *NsG*–419).

Gravity Measurements over the Rhum Tertiary Plutonic Complex

During the past two years, sixty-six new gravity stations were established, using the Imperial College Worden gravity meter, on the islands of Rhum, Eigg, Canna and Sanday in the Inner Hebrides. Local bases on the islands were linked to Pendulum House, Cambridge, through the Mallaig gravity base established by Bullerwell and Phemister (private communication). The results were reduced to the International Gravity Formula, and after correction for terrain effects, the Bouguer anomalies were plotted as a gravity contour map (Fig. 1).

The contours emphasize the intensely local nature of the anomaly, a large positive Bouguer anomaly being centred over the Rhum Tertiary plutonic complex. Over the central ultra-basic mass, the Bouguer anomaly rises to +76·3 milligals, a value which exceeds by 2·9 milligals the largest positive Bouguer anomaly in the British Isles previously recorded by one of us (J. T.) over the Skye Tertiary centre. As all the known Tertiary centres have now been surveyed, it seems unlikely that this value will be exceeded on the remaining unsurveyed land areas within the British Isles. There is, however, always the possibility that similar high positive anomalies may be found over as yet undiscovered Tertiary centres in the sea areas off Northern Ireland and the west coast of Scotland.

Away from the Rhum centre, the Bouguer anomaly decreases rapidly with horizontal gravity gradients exceeding 15 milligals/mile to relatively low values of 5–10 milligals on Canna and Eigg. These values are much lower than the average background anomaly over the

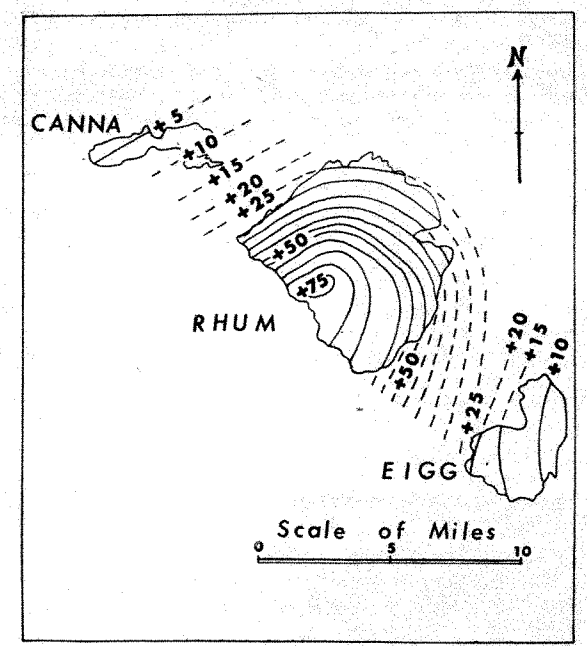

Fig. 1. Bouguer anomaly map of the Islands of Rhum, Eigg, Canna and Sanday in the Inner Hebrides. Contour interval, 5 milligals

Western Isles, and the assumption of a background value of 10 milligals leaves a positive anomaly of 65–70 milligals which requires explanation.

The origin of the anomaly can be interpreted in physical terms by calculating the dimensions and specific gravities of simple models of the gravitating mass and so obtaining a range of theoretical structures capable of producing the observed anomaly. The space form deduced in this way must not only satisfy the numerical characteristics of the anomaly, but must also be consistent with what is definitely known of the geological structure in the area.

As a first step it can be shown, by using the formula for a point mass, that the anomalous mass has a near surface origin, and the most likely cause of the anomaly is a direct density contrast between an extension at depth of the ultra-basic complex seen at the surface and the lighter metasedimentary and granitic layers of the crust. Estimates of the minimum depth to the base can be obtained by assuming: (1) a density contrast; (2) that the anomalous mass is in the form of a vertical cylinder. Calculations were made for vertical cylinders with top surface at datum-level (sea-level) and depth to bottom ranging from 10,000 ft. to 100,000 ft. and for a range of diameters of 5–8 miles. Also, for truncated cones, top surface at datum-level, depth to bottom 44,000 ft., diameter at surface ranging from 5 to 6 miles and a range of inclinations of side.

The results of this analysis were compared with the observed gravity fields, and although further analysis by computer is desirable, it seems probable that the positive gravity anomaly is the result of a dense (and presumably basic or ultra-basic) intra-crustal intrusion having an extension in depth of the order of thickness of the Intermediate layer of seismology (15 km), but having no important horizontal extension beyond the limits indicated by the exposed rocks of the Rhum Tertiary igneous complex.

A better idea of the shape of the mass can be obtained by making certain geological assumptions, namely, that the thickness of Torridonian in the area is 10,000 ft. and that the density of the crust below this depth is 2·75 g/c.c. This analysis indicates that the gravitating mass is best represented by either a vertical cylinder with surface diameter 6 miles, extending downward at least 44,000 ft. (15 km) and having a specific gravity of between 3·05 and 3·10; or, by a truncated cone with a surface diameter

5 miles, extending downward at least 44,000 ft., side inclined to the horizontal at 77°, and having a specific gravity of between 3·05 and 3·10. The surface diameter of the truncated cone model is similar to that of the exposed ring fault, and this model is thought to give a better representation of the probable geological structure.

The lowest permissible specific gravity of 3·05 would indicate that the intrusion is gabbroic; however, by analogy with Skaergaard, it is possible that the body is a heterogeneous complex of a number of rock types, some ultra-basic, some more acid than gabbro.

Gravity surveys by Cook and Murphy[1] and Tuson[2] over other Tertiary centres have yielded similar results, the observed maximum Bouguer anomalies being as follows:

	Milligals
Carlingford-Mourne	58·8 60·8
Skye	73·4
Ardnamurchan	42·0
Mull	71·7
Arran	40·8

This work was carried out with a grant-in-aid from the Royal Society and we thank the Society and Prof. J. G. Bruckshaw of the Imperial College of Science and Technology for the loan of a Worden gravity meter, and Dr. Bullerwell of the Geological Survey and Museum for permission to use some of his unpublished gravity data.

GEOLOGY

Isostatic Recovery in Scotland

The article by Dr. D. F. W. Baden-Powell, on "Isostatic Recovery in Scotland"[1], claims that the evidence there presented makes it possible to decide "between the rival theories of W. B. Wright and Depéret". Dr. Baden-Powell appears to be challenging the theory of isostatic elevation of Scotland and the north of England following removal of the burden of ice in those regions during the glacial period; but he also makes reference to "the supposed recent tilting of the southern parts of Britain".

The evidence is given (albeit perhaps slender) that the marine faunas of certain raised beaches in the south of England and on the west coast of Scotland are similar and that they occur at very broadly similar heights. Although the evidence of the similarity of age and of beach-level is not at all conclusive, it should be pointed out that even unchallenged evidence of this kind would scarcely suffice to support the far-reaching conclusion which Dr. Baden-Powell places on it.

Dr. Baden-Powell appears to be considering the isostatic recovery of Scotland as a single process extending over a period of time which embraces that of the Tyrrhenian beaches. I think that the more generally accepted view would be that during each major glacial period the accumulation of ice over the north of Britain caused an isostatic subsidence of the crust and that in the ensuing warm interglacial period, on the melting of the ice sheets, there followed an isostatic uplift. There have hitherto been recognized in Britain three major glacial periods alternating with interglacials which are referred to as Ipswichian, Hoxnian and Cromerian, and not only the evidence to which attention is directed, but also the more decisive pollen analytic evidence, refers the Nar Valley clay and the Clacton channel deposits to the Hoxnian interglacial. More recent work, however, by West and Funnell in East Anglia has given very strong grounds for supposing that at least two interglacial periods of comparable magnitude preceded the Cromer Forest Bed and were separated from that and from one another by glacial episodes.

The pollen analytic evidence permits an effective reconstruction of the climatic sequences during each of these interglacial periods and in addition leaves very little doubt that the so-called 'Post-glacial period' in which we live has all the characteristics itself of an interglacial period. My own reading of W. B. Wright's theory of isostasy would suggest that during each interglacial the glaciated north of Britain was depressed and that in the ensuing interglacial it experienced isostatic recovery. Correspondingly, during each glaciation the withdrawal of water from the oceans of the world caused a depression of ocean-level of the order of a few hundred feet, recovery from which followed when the general melting of the ice sheets followed at the end of the glaciation and in the early part of the ensuing interglacial period.

Apart therefore from any longer term tectonic processes, one might expect that in the middle and later part of each interglacial both isostatic and eustatic recovery would have been largely accomplished and that there would be time for the cutting of beaches during a period of prevailing warmth. This is the present position, and one can suppose that this has been approximately reached in each of the interglacials. It need not therefore surprise us to find that beaches in the north and south of Britain which are referable to the warm stages of the interglacials should occur at approximately similar heights in relation to present sea-level: to find this is not to invalidate the theory of isostatic elevation.

If we desire to examine the process of isostatic elevation, it is extremely advantageous to concentrate on the evidence of events since the last glaciation, that is to say within the present interglacial period. Here we have not only the advantage that the geological features are largely undestroyed by subsequent events, but we are within the period in which the powerful tools developed in the study of Post-glacial Quaternary geology can give us most assistance, particularly pollen analysis and radiocarbon dating. The Sub-department of Quaternary Research in Cambridge has been occupied for some time past, in association with numerous geologists interested in problems of relative movement of land- and sea-level, in securing precise evidence of the progress and extent of such changes. Some attention has been directed to preliminary findings in the Croonian Lecture[2] and others are in course of preparation for publication. It seems incontestable that major eustatic restoration of ocean-level after the last glaciation had been completed by about 3000–4000 B.C. and that the so-called "25 ft raised beach" of Northern Ireland and southern Scotland was being formed in the period broadly between 6000 and 3000 B.C. during which the rates of isostatic recovery and eustatic rise of sea-level were very similar. It is further apparent that whereas in south-west England and central Wales there has been little uplift since that time, in Scotland and Northern Ireland the beach has been elevated to its present height above sea-level.

Since Dr. Baden-Powell brings in as a "nearly related problem" the tilting of the southern parts of Britain, it may be added that since the end of the maximum eustatic rise of ocean-level, pollen analysis, radiocarbon dating and archæology alike indicate that there must have been substantial relative downwards tilt of the Fenlands and the southern North Sea relative to the west of Britain. That such a tilting may also be, in part at least, due to isostasy, is suggested by the fact that in the region of The Netherlands three phases of marine transgression are recorded for the last three interglacials, and all have deposits at overlapping levels. These are represented by the Holstein Sea, the Eem Sea and the Post-glacial inundations recorded in the Dutch coastal regions and finally by the formation of the Zuyder Zee.

This evidence sufficiently indicates, I believe, the way in which the reality and character of the isostatic uplift of

Scotland can be most effectively explored. It is quite true that hitherto our evidence for the stages of land- and sea-level adjustment prior to the formation of the 25-ft. beach remain largely unexplored; but the new dating techniques, applied to situations where the field geology is adequately known, should give us the means of extending this knowledge to the earlier stages. I believe that it is against the background of this kind of information that Dr. Baden-Powell's most valuable analyses of the interglacial littoral faunas should be viewed.

H. Godwin

Sub-department of Quaternary Research,
Botany School, University of Cambridge.

[1] Baden-Powell, D. F. W., *Nature*, **199**, 546 (1963).
[2] Godwin, H., *Proc. Roy. Soc. Lond.*, B, **153**, 287 (1960).

Prof. Godwin's discussion of my article on the isostatic recovery of Scotland is most welcome, and I am grateful to him for raising several points of interest. But I must start by assuring him that I am not considering this isostatic recovery as "a single process extending over a period of time which embraces that of the Tyrrhenian beaches" as he puts it. On the contrary, I am only discussing crustal movement which has occurred since the last glaciation in Britain, emphasizing the effect this movement would have on the very much earlier Tyrrhenian beaches. (The possibility mentioned by Prof. Godwin of isostatic recovery during interglacial periods raises interesting theoretical questions, but I have never yet seen evidence for such a thing in the field, though of course this does not mean that such events have not taken place.)

As regards Prof. Godwin's reference to the so-called 25-ft. raised beach of Scotland and its relative height farther south, it is well known that the Sub-Department of Quaternary Research in Cambridge has been working hard on this problem for some time; but the height of the 25-ft. beach is not exactly what I was discussing in my article. The point I was trying to make was that W. B. Wright, in his original work reported in the *Geological Magazine* (1911), emphasized the distribution of the 100-ft. beaches in Britain as an important part of his theory about isostasy, believing these beaches to be "grouped round a centre in the Scottish Highlands"; but the work described in my article shows that part of Wright's theory was based on incomplete evidence. For example, according to Wright's map (p. 99), the distribution of both the 'preglacial' and the 'late glacial' 100-ft. beaches is restricted to Scotland, indicating that there is no such thing as a '100-ft. beach' in England. One look at such deposits as the Sussex raised beaches and the Nar Valley clay shows us that we have evidence which was never used by Wright; in this case he was wrong in thinking that a 100-ft. beach ('preglacial') in Scotland descends abruptly to a 10-ft. 'preglacial' beach in southern England.

A minor point made by Prof. Godwin rather mystified me, when he writes that beaches formed during warm interglacial periods could have similar heights in relation to present sea-level, and that this does not invalidate the theory of isostatic elevation. How can this be? Surely uneven uplift of the 25-ft. beach must also tilt the earlier beaches, and the answer must be that so far the measurements of the Tyrrhenian beaches have been too coarse to show the relatively slight movements which have taken place since the 25-ft. beach was formed.

In conclusion, I agree with Prof. Godwin that there has been some differential movement between Scotland and parts of England during the Holocene. I must stress this particularly, as we know that the 25-ft. beach of Scotland is a common feature in the north, whereas this beach is conspicuously absent at that height in southern England.

The single point which I was trying to make in my article was that whatever crustal movement has taken place during the Holocene has been much less than the 100 ft. or so suggested by Wright. It may seem strange to divide a problem like this into parts and try to solve each part in turn, but this seems the best way to set about this complicated subject.

Sir Archibald Geikie once wrote an article with the amusing title: "The Raised Beach of Britain and how Scotland has risen in the World". Perhaps what we are really discussing is whether Scotland has been going up or whether parts of England have been sinking. Presumably W. B. Wright and others have been too ready to assume that both movements have occurred at the same time. As I understand it, Depéret thought that Scotland is at its normal level, with the '25-ft. beach' re-appearing at that height in neighbouring parts of Europe and in the Mediterranean area. In that case a slow abnormal sinking of part of England may be nearer the truth than an extensive rise in the north.

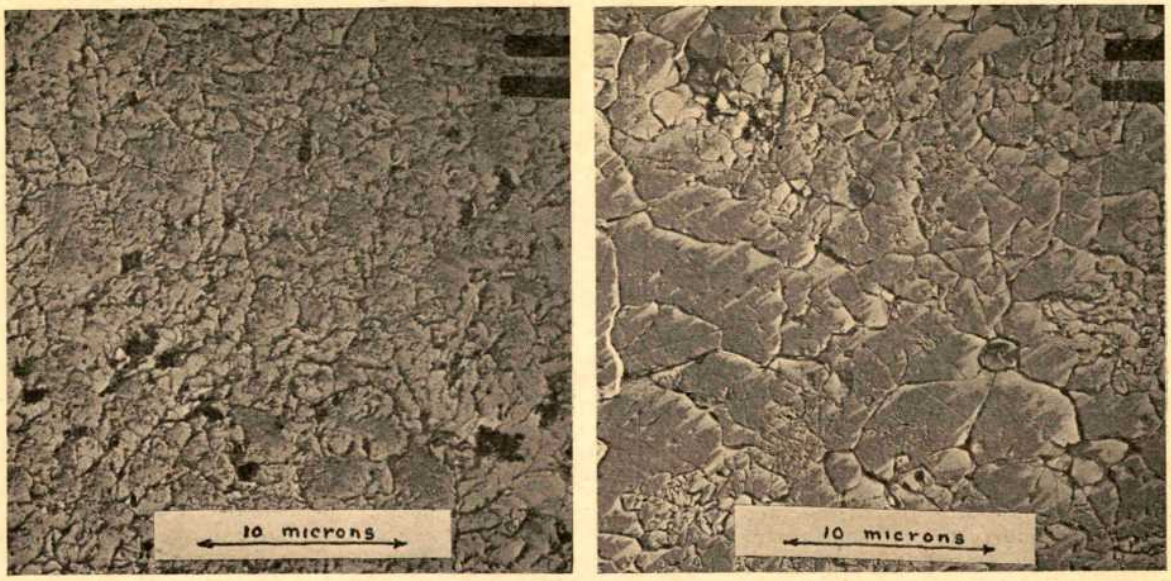
MINERALOGY

Strength and Structure of Flint

In view of the widespread prehistoric use of flint for making tools and weapons, it is of interest to compare its structure and strength with those of present-day ceramic materials. The physical properties of stone tool materials have been investigated by Mary Ellen Goodman[1], who examined and compared the relative density, toughness, resilience and hardness of limestone and a number of siliceous materials. However, the transverse bending strength, needed for quantitative comparison with ceramic materials, was not determined.



Flint is described as a "tough, very compact, microcrystalline material"[2]. The colour varies from light, almost transparent, to grey or black. Weymouth[3] has shown that flint has a typical density of 2·62 g/c.c., and shows only the X-ray diffraction pattern of quartz. Since the density of quartz is 2·65 g/c.c., the material was estimated to have a porosity of about 1 per cent by volume. Microscopic examination showed that flint was similar to chalcedony. The colour was believed to be the result of light scattering from extremely fine pores.

I have myself examined flint cut from the most homogeneous appearing sections of a boulder of English flint obtained through a commercial source; also chalcedony taken from a geode which was almost filled with a brownish, nearly transparent, dense, homogeneous-appearing silica, kindly furnished by Alvin B. Stiles. For comparison, fused silica of the transparent optical-grade, as well as of the opaque type used for laboratory ware, were tested.

Test bars 0·070 in. square, 0·75–1·5 in. long were cut with a '180 grit' diamond saw of 20 mils thickness on a wafering machine; this gave an almost optically smooth finish. Transverse bending strength was measured by applying the loading at a single point at the centre of a test span 0·75 in. long.

Microstructure was examined by embedding specimens in plastic, polishing, etching with dilute hydrofluoric acid, and examining with a metallurgical microscope at a magnification of 500. For electron micrographs, polished sections, etched with hydrofluoric acid, were replicated in two stages with cellulose acetate and carbon, then shadowed with chromium.

Observed transverse rupture strengths of flint and chalcedony are compared in Table 1 with those of some typical ceramics and natural stone materials. It will be noted that the translucent types of chalcedony and flint are about equally strong and that both are stronger than the ceramics, fused silica and porcelain. They are much stronger than the other natural stone materials that are

A B

Fig. 1. Electron micrographs of replicated surfaces of English flint. *A*, dark brown translucent region; *B*, light brown, opaque region

listed. Flint is almost as strong as modern microcrystalline ceramics made by devitrification of glass.

The structure of the dark translucent flint was compared with that of the light brown opaque type. The opaque material occurred as clearly defined, more or less spherical regions within the matrix of the darker translucent mass of the boulder. The translucent regions appeared darker in colour because light penetrated more deeply and was thus absorbed. The spherical shape of the opaque zones suggested that a process of recrystallization might have occurred as though the masses of crystals were radiating from nuclei. This is sometimes seen in the partial devitrification of silica glass.

X-ray diffraction patterns of English flint showed only the presence of quartz. The diffractometer curves showed marked line-broadening in the case of the stronger, dark-brown, translucent specimens, for which an average crystallite size of 120 mμ was estimated. The weaker, light, opaque flint gave sharp lines with no measurable broadening, indicating that the crystal size was more than 500 mμ.

Optical micrographic examination of polished sections in reflected light indicated that the grain size, after etching with hydrofluoric acid, was of the order of 2–10μ in the light opaque areas, but less than 1μ in the dark translucent areas. Electron micrographs of the surfaces of the dark, translucent (*A*) and light, opaque areas (*B*) are shown in Fig. 1. Although the density of these materials ranged from 2·55 to 2·61 g/c.c., suggesting 1·5–4·0 per cent porosity, no pores could be clearly identified. These electron micrographs confirm that the stronger, more translucent type of material has a finer grain structure.

Table 1. Transverse Rupture Strengths

Material	Type	No. of test bars	Strength (lb./in.²) Average		Maximum
English flint	Dark brown, translucent	7	27,000		30,100
English flint	Light brown, opaque	6	17,100		19,800
Chalcedony	Light, translucent	5	23,500		29,100
Chalcedony	Dark, translucent	6	24,000		29,400
Fused silica	Transparent	4	18,400		21,000
Fused silica	Opaque	8	10,300		12,200
Porcelain (ref. 4)	Electrical grade	–	5,000	Range to	15,000
'Pyroceram' (ref. 4)	Code 9606		32,000		
Common stone materials (ref. 5)					
Limestone			500	to	2,000
Marble			600	to	4,000
Serpentine			1,300	to	11,000
Slate			6,000	to	15,000
Granite			1,380	to	5,500
Sandstone			700	to	2,300

Specimens of dark and light regions of chalcedony were both translucent; this indicates that the colour is related to impurities rather than recrystallization. Electron micrographs of the chalcedony showed a fine grain structure indistinguishable from that of the translucent flint. Also, X-ray diffraction indicated a quartz crystallite size of about 200 mμ. Thus the translucent forms of chalcedony and flint appear to be identical.

It is thus concluded that the high strength of flint is a result of its very fine grain structure. The choice of flint by primitive man was undoubtedly based on its outstanding strength in comparison with other stones, as well as its characteristic cleavage behaviour.

I thank D. P. Ferriss, who carried out the petrographic and electron micrographic portion of this study, and O. E. Schupp, who conducted the X-ray diffraction measurements.

PHYSICS

A Ready Method for finding Eccentric Dipole Time

Eccentric geomagnetic dipole[1] time at an observatory (*O*) is defined for present purposes as the difference in eccentric dipole longitude (φ') of the Sun (as distinct from the sub-polar point) and the observatory being measured eastwards from the Sun to the observatory, that is:

$$t_{ecc.} = \varphi'_o - \varphi'_{sun} \qquad (1)$$

Elsewhere[2,3] it has been shown by different approaches that $t_{ecc.}$ runs parallel to ordinary geomagnetic time (a centric system) differing by a constant C_o, which is a characteristic of the observatory for the particular epoch of the Earth's magnetic field. Thus, also:

$$t_{ecc.} = \varphi_o - \varphi_{sun} + C_o \quad (2)$$

where φ represents geomagnetic longitude.

$$C_o = \varphi'_o - [\varphi'_o]_{X=Y=Z=0} \quad (3)$$

where[3]:

$$\tan \varphi'_o = \frac{0{\cdot}854\ (\sin\theta_o \cos\varphi_o - X) - 0{\cdot}495\ (\sin\theta_o \sin\varphi_o - Y) - 0{\cdot}160\ (\cos\theta_o - Z)}{-0{\cdot}515\ (\sin\theta_o \cos\varphi_o - X) - 0{\cdot}848\ (\sin\theta_o \sin\varphi_o - Y) - 0{\cdot}126\ (\cos\theta_o - Z)}$$

$X = -0{\cdot}0577$, $Y = 0{\cdot}0320$, $Z = 0{\cdot}0184$ for epoch 1955·0 and (θ_o, φ_o) are geographic co-ordinates of the observatory.

The point of the present communication is to indicate that eccentric dipole time can be found to a useful accuracy for many purposes by a semi-graphical method. Knowing the universal time, the equation of time and the solar declination, the position of the sub-solar point can be found on a map containing both geographic and ordinary geomagnetic grids for the epoch. $\varphi_o - \varphi_{sun}$ is then easily and quickly found. The constant C_o for the observatory, calculated once, is available then for all determinations of $t_{ecc.}$ in that epoch.

Note, in passing, that grids of eccentric dipole co-ordinates cannot be used directly in this manner to find $t_{ecc.}$ because the longitude of the sub-solar point (as given by Greenwich hour angle and declination) is not in the eccentric dipole longitude plane containing the Sun.

Recently Brice and Ungstrup reported[4] the use of a new and different type of time. They define 'auroral' time for a hemisphere by a centric system the axis of which passes through the 'centre' of the auroral zone of that hemisphere. They thus arrive at two different centric systems of time, one for each hemisphere. This dichotomy seems unwieldy and perhaps unnecessary in view of the fact that the eccentric dipole poles[1] are at approximately the centres of the respective auroral zones[5,6] together with the established concept of the eccentric geomagnetic dipole. Eccentric dipole time has the advantages of 'auroral' time combined with the desirable element of magnetic conjugacy, which is known to occur with many high-latitude phenomena. It has also the advantage of global applicability.

Electrical Conductivity of Ammonium Perchlorate

Zirkind and Freeman[1] have pointed out the increase in the electrical conductivity of ammonium perchlorate crystals on irradiation with 0·637-MeV cæsium-137 γ-rays. In this communication, results are reported from an investigation of the electrical conductivity of ammonium perchlorate solid as a function of temperature and gaseous atmosphere. Data concerning the electrical conductivity of ammonium perchlorate were not found in the literature.

Reagent grade ammonium perchlorate was twice recrystallized from distilled water. The samples were dried overnight at 110° C and compressed into disk-shaped pellets, 0·5 in. in diameter and 0·125 in. in depth. The pellets were annealed overnight under a vacuum of 0·01 mm mercury at 110° C. This treatment was found necessary in order to obtain reproducible results. Silver paint electrodes were used. The ends of the disks were completely silvered. Two leads were connected to the electrodes by means of the silver paint. One lead consisted of a chromel-alumel thermocouple junction, which also served to measure the temperature of the pellet. The other lead is a copper wire. The wired disk is placed in a 'Pyrex' vessel which is heated by a resistance furnace. Resistivity measurements were made with a General Radio 1230 *ADC* amplifier and electrometer.

The electrical conductivity of different samples varies within a factor of 2 under similar experimental conditions and temperature. This variation may, in part, be due to the irreproducibility of the surface contacts and of the mechanical treatment which is known to influence the conductivity of solids[2]. In this work the temperature dependency of the electrical conductivity under vacuum in oxygen and argon was determined. Each complete series of experiments was conducted on a single sample. The conductivity measurements were made over the temperature range of 25° C–125° C. Furnace temperature was raised continuously at the rate of 2° C/min.

The three curves in Fig. 1 show the electrical conductivity of ammonium perchlorate as a function of temperature under vacuum (0·01 mm mercury; in an atmosphere of oxygen (pressure 1·00 mm mercury); and in argon (pressure 1·00 mm mercury). These curves show that argon and oxygen depressed the electrical conductivity of ammonium perchlorate approximately one and two orders of magnitude, respectively. The activation energies determined from curves I, II and III were 1·10, 1·15 and 1·40 eV, respectively. The calculation was based on the relationship:

$$\sigma = \sigma_0 \exp(-E^*/RT)$$

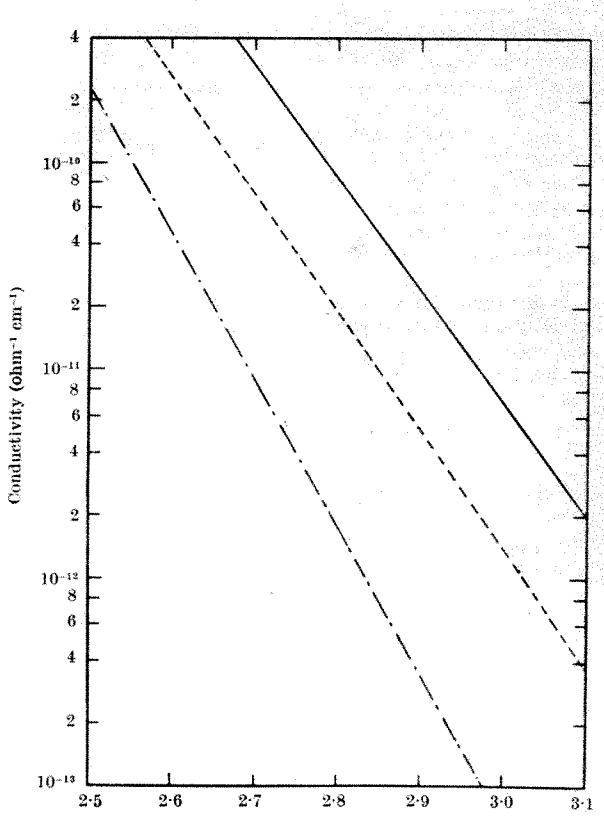

Fig. 1. Temperature dependency of the electrical conductivity of ammonium perchlorate pellets

	Pressure (mm mercury)	Atmosphere
———	0·01	Air
– – – –	1·00	Oxygen
—·—·—	1·00	Argon

where: σ = electrical conductivity; E^* = activation energy; R = Boltzman constant; T = absolute temperature.

It was found that the electrical conductivity results were reproducibly reversible to within ±10 per cent of the original values in going repeatedly from vacuum to argon to oxygen. An activation energy of about 1·1–1·4 eV appears reasonably close to what one may expect for the ionic conductivity of ammonium perchlorate. In the case of the alkali metal halides[3], the activation energy is higher, approximately 2·0 eV as may be expected. This may be an indication that the electrical conductivity of ammonium perchlorate is primarily ionic; however, this cannot be concluded based on the foregoing results. If it is ionic conduction then oxygen and argon are probably trapping cation vacancies. If it were electronic then there would be a transfer of electrons from the solid to the adsorbed gases. Experiments are being conducted to resolve these questions.

This project was supported, in part, by the Defense Atomic Support Agency under Nuclear Weapons Effects Research Sub Task No. 06.032.

Spectra of Giant Pulses from a Ruby Laser

THE spectral character of the giant pulse[1] emitted by a ruby laser has been investigated to determine the suitability of this source for plasma light scattering experiments. A 'Trion *LS*-4 laser' system consisting of a 10 cm × 1·3 cm × 1·3 cm total internal reflexion ruby with 90° *c*-axis orientation, pumped by means of a 10,000 joule spiral xenon flash-lamp, has been modified to produce giant pulses by the addition of a Kerr cell, a Nicol prism, and a 48 per cent reflectivity dielectric mirror acting as external reflector. Giant pulses which last for less than 40 n sec were produced by switching the Kerr cell with a low inductance thyratron circuit. The Kerr cell was normally gated open for 1 μsec. Throughout the experiment the pumping energy delivered to the flash-lamp was maintained at 6,700 ± 300 joules, which is about 25 per cent above threshold for normal relaxation oscillations in this crystal at the temperature at which it was operated, namely 126 ± 3° K. High-resolution spectroscopy of these pulses was carried out with a variable gap silvered Fabry–Perot interferometer which had a resolving limit of 0·011 cm^{-1} for 1 cm separation of the mirrors. To ensure that only giant pulse light was recorded, a Barr and Stroud framing camera operated at a speed of 10 μsec per frame was used to photograph the interference fringes on Gaevert infra-red sensitive film ('Scientia 52*A*86').

With Fabry–Perot spacings of 2·78 cm and 4·05 cm, giving free spectral ranges of 0·18 cm^{-1} and 0·12 cm^{-1} respectively, we obtained fringe patterns (Fig. 1) which typically fill between 1/2 and 2/3 of an order. They are composed of several lines, usually 4 or 5 although occasionally 3 or 6 have been observed. Relative wave-number spacings and intensities varied from pulse to pulse.

D'Haenens and Asawa[2] have found that the relaxation oscillations of a ruby laser often consist of components which they have identified with axial modes within the crystal cavity. Moreover Hughes[3] has shown that an individual laser spike may contain several modes. We have tried to relate the line structure which we have observed in the giant pulse fringes to possible longitudinal modes in the laser cavity. The condition that a standing wave be set up in the axial mode in a cavity of optical length S is that an integral number, N, of half-wave-lengths can be fitted into S, that is, $2S = N\lambda$. It follows that a shift ΔN in the number of half-wave-lengths gives rise to a shift in wave number, $\Delta\bar{\nu}$, given by $2S\,\Delta\bar{\nu} = \Delta N$.

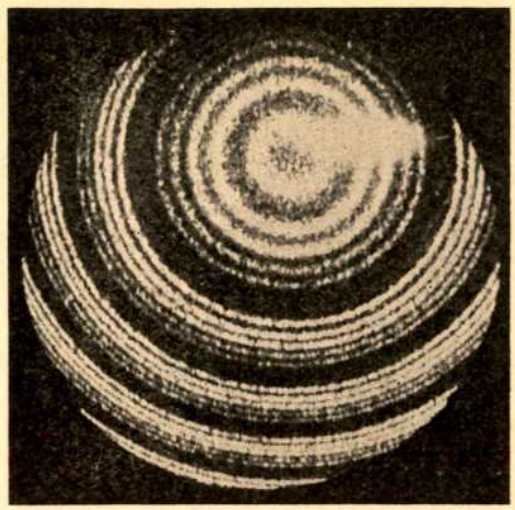

Fig. 1. Fringe pattern of ruby laser giant pulse scattered by a ground-glass screen. Interferometer separation 2·78 cm. Framing camera operated at 10 μsec per frame

We have examined the spacing of the lines contained within a single order and found that the wavenumber separations are frequently small integral multiples of the characteristic $\Delta\bar{\nu}$. To confirm this result the mode separation was varied by changing the optical length of the cavity. As an example we present the results obtained from two pulses both of which resulted in fringes composed of five constituent lines. One of these is illustrated in Fig. 1. In the first case, the optical length of the laser cavity was 77 cm, corresponding to a characteristic $\Delta\bar{\nu} = 0{\cdot}0065$ cm^{-1}; in the second it was 91 cm, corresponding to $\Delta\bar{\nu} = 0{\cdot}0055$ cm^{-1}. Table 1 lists the separations between pairs of lines in the fringes in units of the appropriate $\Delta\bar{\nu}$. The letters *a*, *b*, *c*, *d*, *e* refer to the lines in the fringe in order of increasing wave-length. It will be observed that apart from a set of four pairs in both cases, arising in each instance from a single line, that labelled '*b*', the values of ΔN are very close approximations (measuring error ± 0·03) to integers, and we regard this as evidence that they arise from axial cavity oscillations. Nearly every family of axial modes which we have examined seems to be accompanied by a line, like '*b*' in Table 1, which cannot be fitted into the mode pattern. Occasionally more than one outsider of this sort appeared, and once we observed two distinct sets of modes accompanied by one outsider which was a member of neither.

We have not found a family of more than four modes nor have we found a pair of modes separated by less than 3 $\Delta\bar{\nu}$. The limit of resolution for mode separation was set

Table 1

Exp. 1 $\Delta\bar{\nu}$ = 0·0064 cm^{-1}		Exp. 2 $\Delta\bar{\nu}$ = 0·0055 cm^{-1}	
Line pair	ΔN	Line pair	ΔN
ab	4·30*	*ab*	2·31*
ac	8·01	*ac*	5·04
ad	12·0	*ad*	9·00
ae	15·1	*ae*	14·06
bc	3·71*	*bc*	2·68*
bd	7·74*	*bd*	6·67*
be	10·9*	*be*	11·7*
cd	3·95	*cd*	3·99
ce	7·10	*ce*	9·04
de	3·10	*de*	5·05
	± 0·03		± 0·03

by fringe width, which varied between 0·004 cm^{-1} and 0·018 cm^{-1}, so it is possible that separations of one or two $\Delta\bar{\nu}$ may not have been detected. This, however, would not explain those lines which did not fit into a mode family as their widths were in general not broad enough to contain multiplets. No family of modes extending over a range of wavenumber greater than 18 $\Delta\bar{\nu}$ has been found. That modes separated by higher multiples of $\Delta\bar{\nu}$, but disguised by overlapping of orders in the Fabry–Perot pattern, were not present was confirmed by carrying out a number of trial shots with an interferometer spacing of 2 cm and 0·1 cm. The former spacing would have brought to light members of a family of axial modes over a range of about 40 $\Delta\bar{\nu}$, and the latter, which produced fringes the widths of which were at the limit of instrumental resolution, served to show that over a range of about 800 $\Delta\bar{\nu}$ no more modes were present.

The occurrence of single unrelated lines and more than one family of axial modes in a single giant pulse may be due to different parts of the laser oscillating independently. It is interesting to note that if the fringes are considered as arising from single modes, the observed widths are consistent with mode lifetimes of between 2 and 8 n sec.

ENGINEERING

Reversed Plastic Flow during the Unloading of a Spherical Indenter

The process of indentation of a metal surface by a hard spherical indenter has been examined in considerable detail by Tabor[1] and others. If the indenter makes contact with the surface over a circular area of radius a under the action of a load W, the mean contact pressure $p_m = W/\pi a^2$. Tabor showed that plastic yielding begins beneath the surface of the metal when p_m reaches the value 1·1 Y (where Y = yield stress of the metal in simple tension). As the load is increased and a marked plastic indentation develops, the mean pressure approaches a value which is independent of the load given by:

$$p_m = cY \qquad (1)$$

where c has a value of approximately 3. This is the state of affairs in a Brinell hardness test.

After the load and indenter are removed the indentation remains, although its curvature is slightly less than that of the indenter itself. The change in curvature is attributed by Tabor to elastic recovery of the material during unloading and his measurements are consistent with this view. If the unloading process is elastic then reloading to the same load should produce no further plastic deformation. Tabor observed no increase in the size of the impression during five repeated applications of the same load. He concluded, therefore, that the deformation after the first application of load was entirely elastic.

Some recent experiments made by Tyler, Burton and Ku[2], in which an impression has been observed to grow in size under the action of a load repeated many times, have led to Tabor's conclusions being re-examined. It is the purpose of this communication to show, on theoretical grounds, that reversed plastic yielding would be expected during the unloading of an indenter, and hence that repeated loading would cause a continuous cycle of plastic deformation.

When the load is first applied the mean contact pressure is given by equation (1), but no exact theory predicts the distribution of this pressure over the contact surface. Tabor[1] quotes the approximate analysis of Ishlinsky to demonstrate that the actual pressure distribution will not differ greatly from the elliptical distribution of Hertz for elastic contact. The unloading process may then be thought to consist of the subsequent application of an equal negative pressure to the contact surface.

At the end of the loading process the material beneath the surface, lying on the axis of symmetry, will be in a state of plastic flow, so that by the Tresca maximum shear criterion of yield:

$$\sigma_z - \sigma_r = Y \qquad (2)$$

where σ_z is the stress (compressive) acting normal to the surface and σ_r is the stress (also compressive) acting parallel to the surface.

To represent unloading we apply a Hertzian distribution of tension to the surface having a maximum intensity:

$$p_0 = \frac{3}{2} p_m = \frac{3}{2} cY \qquad (3)$$

If the unloading process were perfectly elastic this surface tension would result in a maximum principal stress difference at a point beneath the surface on the axis of symmetry the magnitude of which is given by the Hertz theory, that is:

$$(\sigma_z - \sigma_r)_{\max} = 0{\cdot}62 p_0 = 0{\cdot}92 cY \qquad (4)$$

in which σ_z and σ_r are both tensile.

To find the state of stress corresponding to complete unloading we superpose the stresses given by equations (1) and (4), having due regard for sign, with the result:

$$\sigma_z - \sigma_r = (1 - 0{\cdot}93c)Y \qquad (5)$$

Now reversed yielding would be expected if $\sigma_z - \sigma_r$ in this equation exceeds $-Y$, that is, if:

$$c > 2{\cdot}15 \qquad (6)$$

As Tabor has shown by many tests, c has a value lying between 2·7 and 3. We would therefore expect reversed yielding to occur in a small region beneath the surface during unloading from the fully plastic state. This yielded region will be fully contained and will not make a noticeable change in the surface profile, which explains why it was not detected by Tabor's profile measurements.

By the same argument, a second loading to the same maximum load will cause a reversal of yield in the subsurface region. Under cyclic loading, therefore, we would expect a repeated cycle of plastic deformation. This could lead to either a progressive enlargement of the indentation or failure by a fatigue process.

The foregoing argument is based on the assumption that the metal has an equal yield strength in loading and unloading. Actually the Bauschinger effect will make reversed yielding during unloading even more certain.

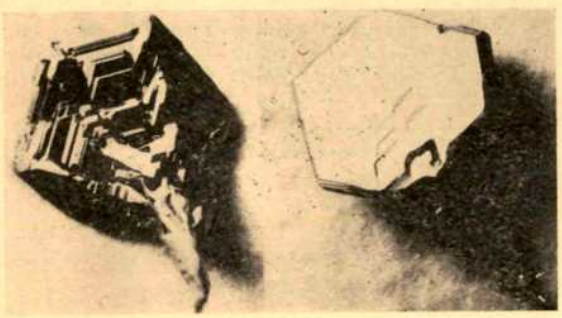
METALLURGY



Crystal Growth of Titanium

TITANIUM, grown by the electro-refining method from molten salt at temperatures below the transformation point (870° C), crystallizes in various dendritic shapes, namely, needles and flakes. It crystallizes in various forms based on single crystals or on compound crystals, and each surface is bounded by a definite plane.

So far, crystallographic investigations have been carried out only on crystals of simple shape[1-3] and grown in a fused salt bath at a higher temperature than the transformation point[4]. We have carried out systematic investigations of hexagonal titanium crystals of complicated shapes growing under various conditions of electrolysis.

Crystals were grown in a fused salt bath of alkali halide by electrolysis, using impure titanium (Brinell hardness No. 150–200), as a soluble anode, at temperatures of 850°–680° C and at current densities of 30–300 amp/dm². Under these conditions, flake crystals grew to a size of 1 mm in thickness and about 10 cm² in area, while needles grew as large as 1–2 mm in diameter and a few centimetres in length.

A flake crystal grown from the molten salt is shown in Fig. 1, where development of the basal plane can be seen:

a *b*

Fig. 1. Development of the basal plane in a titanium crystal. *a*, Rapidly growing side with marked steps; *b*, slowly growing side. (× *c*. 2·5)

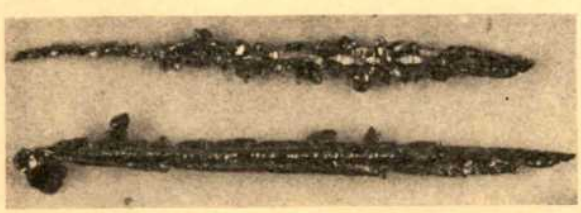


Fig. 2. Titanium crystals grown from molten salt by electrolysis. The crystals grown in needles are parallel to < 10$\bar{1}$1 > direction. (× *c*. 2·5)

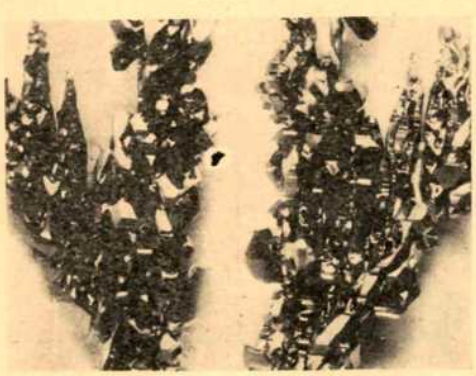

Fig. 3. A dendrite of titanium with two growth axes. (× 2)

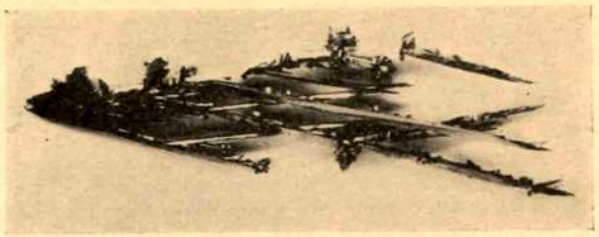

Fig. 4. Dendrites of titanium grown by electro-refining. Each branch is parallel to < 1$\bar{1}$03 >. (× 1)

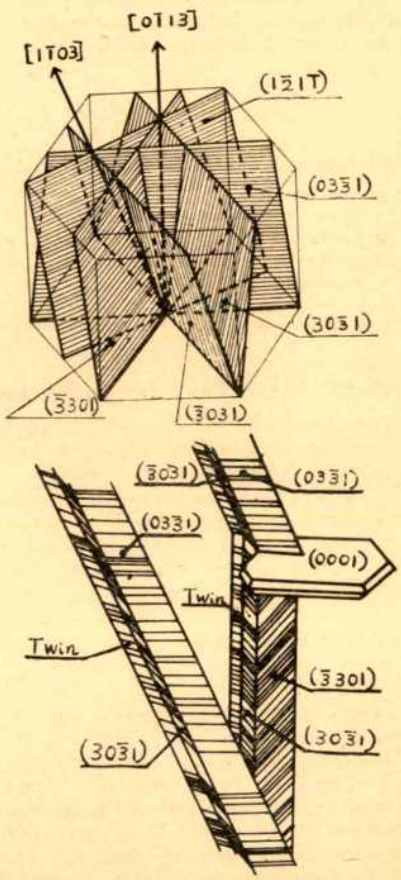

Fig. 5. Schematic representation of a dendrite with < 1$\bar{1}$03 > growth axes. Each branch consists of two thin, twin-related crystals

the step planes of the crystal are {1$\bar{1}$02}, {1$\bar{1}$03} and {1$\bar{1}$04}, while the growth direction is parallel to < 11$\bar{2}$0 >.

In titanium, < 11$\bar{2}$0 > is a close-packed direction, and one would expect that the direction of growth of needle crystals would coincide with this direction; but this was seldom observed. Most needle crystals obtained from the molten salt have a shape similar to that shown in Fig. 2, where it should be noted that the direction of growth is parallel to < 1$\bar{1}$01 >: such a needle crystal is bounded by the ($\bar{1}$101), (01$\bar{1}$1) and ($\bar{1}$012) faces.

The dendrite shown in Fig. 3 consists of needles that grew in the [10$\bar{1}$1] and [2$\bar{1}\bar{1}$2] directions on the ($\bar{1}$012) plane; these are bounded by the ($\bar{1}$101), ($\bar{1}$012), and (0$\bar{1}$11) faces.

In some cases, one obtains a dendritic crystal, as is shown in Fig. 4. These are characterized by pillar-shaped needles (such a compound crystal is shown schematically in Fig. 5).

In general, we found that the crystals grown from the high-purity salt were bounded by the basal planes and planes of the type [10$\bar{1}l$] (here l can be 1, 2, 3 or 4). The

crystals grown from the impure salt were bounded by the basal planes, {10$\bar{1}$1} planes and prismatic planes—such as {30$\bar{3}$1}, {30$\bar{3}$2}, etc. Crystals grew in thin plates when they were deposited from the molten salt at temperatures of 750°–850° C and at low current densities (less than 100 amp/dm²); in such cases their directions of growth were parallel to the basal plane. However, crystals grew in needles when they were deposited from the molten salt at temperature below 750° C with current densities greater than 150 amp/dm²; under such conditions their directions of growth were parallel to $<1\bar{1}01>$, $<1\bar{1}22>$ or $<1\bar{1}03>$.

Growth twins were frequently observed, their twinning planes being {10$\bar{1}$1}, {10$\bar{1}$2}, and {11$\bar{2}$1}. It is unusual to observe the {10$\bar{1}$1} plane as a twinning plane in the case of growth twin, and so far as we know such a situation has not been previously reported for deformation twins[3,5].

Liquid Metal Heat Transfer in Packed Beds

Investigations of heat transfer in liquid metal irrigated packed beds counter current to gases do not appear to have been, so far, reported in the literature. Yet, the problem is of unquestionable interest in extractive metallurgy, as was shown by Shu-p'ei[1] in his discussions on the iron blast furnace.

The apparent absence of liquid metal heat transfer investigations in packed beds may perhaps be explained by the experimental difficulties of preventing the occurrence of simultaneous mass transfer effects and/or separating the two phenomena analytically from the combined results. It is, however, suggested that useful insight into the foregoing phenomenon could be obtained with ambient, or slightly elevated temperature systems in which the Dufour effect could be justifiably considered unimportant. Mass transfer studies by Warner[2] concerning the absorption of zinc vapour in molten lead flowing through a bed packed with steel Raschig rings have shown the usefulness of this type of investigation. The extension of his work to heat transfer studies in similar systems appeared logical. To this end, in co-operation with Dr. N. A. Warner at the University of New South Wales, I have carried out some heat transfer experiments in beds of different packings irrigated with mercury counter current to various gases. Although many difficulties had to be overcome and some problems still remain to be solved, the results of the studies indicate, *inter alia*, that the transfer is predominantly gas phase controlled and the data could be correlated, with some degree of accuracy, by a Nusselt type expression. The actual correlation featured a liquid hold-up term in addition to the usual moduli which, except for Prandtl number, were modified to account for the unknown heat transfer area involved.

Investigations are at present in progress using a fusible alloy to study the various unsolved problems of heat transfer investigations with mercury. These include the elucidation of the part played by the packing in the heat transfer mechanism and by the various parts of the liquid hold-up, and, the evaluation of the exponent of $Cp\mu/k$, which in the investigations with mercury was assumed to be equal to 0·33.

One of the findings of the work on mercury that is unlikely to be altered appreciably by future results is the apparent heat transfer efficiency of these systems when compared with tubular exchangers or certain fluidized beds and spray columns.

Twinning at 77° K of 'Flash-annealed' Niobium

Niobium is known to twin at 77° K, and for the purest reported[1] the estimated lower yield stress was ~40 kg mm^{-2} and the maximum tensile stress only a little higher. For specimens of this purity the lower yield stress at room temperature was ~7 kg mm^{-2}.

At about this strain rate the yield stress of niobium free of impurities is predicted[2] to be ~2·5 kg mm^{-2} and this is postulated to be the Peierls–Nabarro force. Considering this model, the yield stress of this 'pure' niobium at 77° K should be ~50 kg mm^{-2}.

Using a 'flash-annealing' technique the proportional limit of niobium foils strained at 1 per cent min^{-1} was lowered to ~3·5 kg mm^{-2}. This material was strained at 77° K (liquid nitrogen bath) and one or more of the following phenomena was found to occur for specimens taken from the same foil. Proportional limit was some-

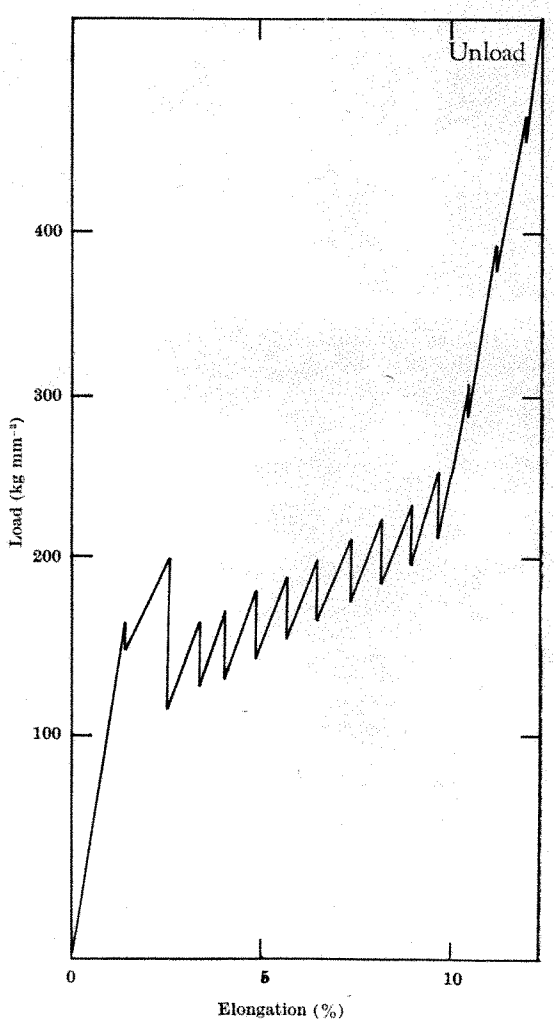

Fig. 1. A load-elongation curve at 77° K of 'flash-annealed' niobium

times found to be ~50 kg mm^{-2}, but twinning occurred before and/or after this stress value. As twinning sometimes commenced at a stress level of ~20 kg mm^{-2}, the magnitude of the Peierls–Nabarro force cannot be as great as originally supposed if a dislocation model for twinning is assumed. Maximum tensile stress was sometimes only a little higher than 50 kg mm^{-2}, but with other specimens profuse twinning continued for appreciable extension. The maximum stress recorded (Fig. 1) was ~500 kg mm^{-2} when the specimen was unloaded, this being the limit of the load cell. Twinning was identified metallographically at all stress values.

RADIOCHEMISTRY

A Simple Preparation of 5-Iodo-2′-deoxyuridine labelled with Iodine-131 using Iodine Monochloride

Methods so far described for the preparation of 5-iodo-2′-deoxyuridine are based either on the iodination of deoxyuridine by free iodine in the presence of an oxidizing acid or free iodine in an alkaline medium[1–3]. The compound labelled with iodine-131 has been obtained by adapting the iodination in acid[1,4] but the specific activity of the product has not been reported.

The method described here gives consistent yields of 65–70 per cent of 5-iodo-2′-deoxyuridine and iodine-131 uptakes of 55–60 per cent of the iodine-131 used. The method is suitable for preparing mg quantities having a high specific activity.

Carrier-free Na ^{131}I in aqueous solution, obtained from the Radiochemical Centre, Amersham, was placed in a conical 10-ml. stoppered test-tube. The water was evaporated by placing the tube in a water-bath at about 40° and gently blowing a stream of nitrogen over the solution. In order to avoid loss of radioactivity the nitrogen was turned off immediately after the last trace of water had disappeared. For pilot experiments approximately 0·05 μc. was used and in preparations for biological use between 500 μc. and 1 mc. were used.

For each preparation a fresh solution of iodine monochloride[5] in acetic acid, 0·0162 g/ml., was made. For the iodination of 1 mg deoxyuridine, 0·066 ml. of this solution containing 1·5 equivalents was used. The solution was placed in the test-tube which was stoppered and heated in a water bath at 60° for 1 h to effect exchange of ^{131}I and stable iodine. The tube was cooled to room temperature and 1 mg deoxyuridine (grade II obtained from Sigma Chemical Co.) was added. The tube was stoppered and heated in the water bath for a further 1½ h at 60° with occasional gentle shaking. If the bath temperature exceeded 65° there was a tendency for some of the iodine chloride solution to evaporate from the reaction mixture and condense on the glass stopper, giving rise to erratic results. After cooling to room temperature 1 ml. of water was added to the reaction mixture. The resulting solution was adjusted to about *p*H 10 by careful addition of N sodium hydroxide using phenolphthalein as an internal indicator. The product was purified by placing the alkaline solution on a column of 'Dowex resin *A.G.*1' (formate form; × 2; 200–400 mesh, manufactured by the Bio-Rad. Corp.), 2 cm long and 1 cm in diameter[3].

The column was washed with 15 ml. 0·01 N sodium hydroxide, which removed a small amount of iodine-131 containing impurity and eluted with 0·1 N formic acid in 2 ml. fractions. Unchanged deoxyuridine came off in the first 6 ml. of eluate. The next 20 ml. of eluate contained 95 per cent of the radioactivity which could be eluted with 0·1 N formic acid. The radioactivity was measured in a well-type scintillation counter.

The phenolphthalein and unreacted ^{131}I-iodide were retained by the resin. The yield of 5-iodo-2′-deoxyuridine was determined by measuring the ultra-violet absorption of the solution at 288 mμ in a Unicam model 500 spectrophotometer.

The purity of the product was checked by comparing it with authentic material (California Corp. for Biochemical Research) by descending chromatography in ethyl acetate saturated with phosphate buffer (0·05 M, *p*H 6·0)[3].

The radioactivity on the chromatogram was counted in an automatic chromatogram scanner. The main peak was followed by a small peak which contained 10 per cent of the total activity.

I thank Dr. R. Pitt-Rivers for helpful discussions.

CHEMISTRY

Occurrence in Egg Yolk of Plasmalogenic Triglycerides

Evidence has recently been obtained for the existence of a new class of glycerides containing a vinyl ether linkage. Such glycerides were extracted from the digestive glands of *Asterias forbesi*, the common starfish[1,2], and from the milk fat, beef tallow and ox heart[3]. According to Kiyasu and Kennedy, such neutral plasmalogens may be named plasmalogenic diglycerides and plasmalogenic triglycerides respectively[4].

The present report describes the isolation from egg yolk of a plasmalogenic triglyceride to which the tentative structure I could be assigned:

$$\begin{array}{l} CH_2\text{—}O\text{—}CH{=}CH\text{—}(CH_2)_{15}\text{—}CH_3 \\ | \\ CH\text{—}O\text{—}CO\text{—}R_1 \text{ (or } R_2) \\ | \\ CH_2\text{—}O\text{—}CO\text{—}R_2 \text{ (or } R_1) \end{array} \qquad \text{(I)}$$

$R_1 = CH_3\text{—}(CH_2)_{14}$, $R_2 = CH_3\text{—}(CH_2)_{16}$

In two different runs, dry hen eggs and fresh egg yolks were extracted successively with acetone, diethyl ether and boiling ethanol. The acetone extracts contained about 96 per cent of the total extractive material and were discarded. The combined ether extracts furnished a colourless, crystalline solid which was recrystallized from 95 per cent ethanol. Working up the mother liquor by crystallization, chromatography of the resulting substance over activated alumina, followed by recrystallization from acetone, gave colourless prisms, m.p. 34°–39°. The yield of the thus obtained substance I was about 100 mg from 4 kg dry eggs.

The following chemical and physical data were decisive for the establishment of the structure I. The lipide contained no phosphorus. Carbon–hydrogen analysis, calculated for $C_{55}H_{106}O_5$: C, 77·9; H, 12·6 per cent; found C, 77·3; H, 12·2 per cent. Catalytic hydrogenation in the presence of Adams platinum catalyst raised the m.p. to 54°–57°. A spot test for aldehydogenic substances with 2,4-dinitrophenylhydrazine[5] was positive. The infra-red

absorption spectrum taken in nujol showed a characteristic strong peak at 1,100 cm^{-1} attributable to 'C–O–C' deforming, a strong ester carbonyl absorption at 1,740 cm^{-1}, and a medium absorption at 1,650 cm^{-1} which is attributable to 'C=C' stretching. There was no band in the hydroxyl region near 3,600 cm^{-1}. The combined alkaline and acid hydrolysis gave a mixture of fatty acids and aldehydes. They were converted into both methyl esters and dimethyl acetals and subjected to vapour-phase chromatography. The gas-chromatographic analysis was carried out on an Aerograph Wilkens *A*–90 *C* instrument. A silicone 5-ft. column was operated at 225° with hydrogen at a flow rate of about 30 ml./min. The records indicated the presence of hexadecanoic acid, octadecanoic acid and octadecan-1-al.

The present evidence, taken in conjunction with the results reported previously[1–3], gives the structure I for the lipide from egg yolk. On the basis of the investigations reported so far, it is likely that this new class of lipids is widely distributed in Nature.

Electrical Conductivity of Solutions of Aluminium (III), Gallium (III) and Indium (III) Iodides in Alkyl Iodides

Several investigations have been devoted to the electrical conductivity of aluminium halides in alkyl halide solutions[1–5]. The conductance of these solutions has been attributed to the formation of some complexes or addition compounds composed of both interacting molecules. No investigations on analogous systems with gallium and indium halides have hitherto been performed. In order to gain more information of the nature of interaction of MI_3 with RI, where M is aluminium, gallium or indium and R is an alkyl radical, the conductances of the solutions of aluminium, gallium and indium triiodides in anhydrous methyl, ethyl and propyl iodides were studied. It should be noted that particular attention has been directed to a thorough purification and drying of the reagents, the electrical conductivity being very sensitive to even small concentrations of various impurities.

The determined values for seven investigated solutions, the molar ratio MI_3 : RI being always $4{\cdot}2 \times 10^{-3}$, are presented in Table 1. From the experimental results it can be readily seen that MI_3 are weak electrolytes in alkyl iodides, and that the complex compounds in these solutions, if actually present, have a very weak polar character.

Since the electrical conductivity of the systems under investigation increases with time (rapidly during the first 20–40 min, then slowly during a long period of time), the specific conductivity values given in Table 1 were obtained by using the extrapolation method (for $t = 0$) described by Fairbrother and Scott[5]. These authors have attributed the increase of the conductivity of $AlBr_3$—C_2H_5Br solution to a certain chemical reaction leading to the formation of hydrogen bromide, which could be volatilized off with the ethyl bromide and detected. In order to test this hypothesis as regards AlI_3—C_2H_5I solution we have investigated the chemical composition of the vapours in equilibrium with the solution, using a mass spectrometric technique. However, the proportion of the peak heights of ethyl iodide and hydrogen iodide undergo only very slow changes during more than 70 h. Thus, the rapid rise in conductivity of AlI_3—C_2H_5I system cannot be explained in the way proposed by Fairbrother and Scott.

Table 1. Specific Conductivity of MI_3—RI Solutions (M = Al, Ga, In, R = Methyl, Ethyl, Propyl)

Solution	Specific conductivity × 10^{-7} ohm^{-1} cm^{-2}
AlI_3—CH_3I	5·4
AlI_3—C_2H_5I	6·2
AlI_3—C_3H_7I	3·1
GaI_3—C_2H_5I	5·1
GaI_3—C_3H_7I	2·3
InI_3—C_2H_5I	7·0
InI_3—C_3H_7I	6·0

A more detailed description of the present work will be published shortly.

We thank Prof. I. Zlotowski, head of the Department of Nuclear Chemistry, University of Warsaw, for a number of discussions and suggestions.

Effect of Electron Donors on the Isotopic Exchange between Aluminium (III), Gallium (III) and Indium (III) Iodides and Alkyl Iodides

Very few investigations have been devoted to the isotopic exchange reactions of halogens in AlX_3—RX solutions[1], where X is a halogen atom and R is an alkyl radical. No work on analogous systems with gallium and indium halides has hitherto been published. In the work recorded here, the isotopic exchange reactions of iodine between aluminium, gallium and indium triiodides and methyl, ethyl and propyl iodides have been studied. It should be noted that the reagents were purified and dried with the greatest possible care. The experiments have been carried out in 'all glass' vacuum apparatus, at temperature $20 \pm 1°$ C, the molar ratio MI_3 : RI varying from 4×10^{-3} to 6×10^{-3}. The metal iodides were labelled with iodine-131.

The exchange rate was notable in each of the nine investigated systems. In the $Al^{131}I_3$—CH_3I solution (the fastest exchange) the equilibrium is reached within less than one minute, while in the $In^{131}I_3$—C_3H_7I solution (the slowest exchange) the fraction exchange is equal to 0·11 at the end of the first minute. The exchange rate decreases with the increase of the atomic number of the metal and the size of the radical.

The addition of small amounts of an electron donor substance (for example, ethyl alcohol, ether, etc.) to the alkyl iodide causes strong 'exchange blocking'. For example, if per each mole of aluminium triiodide 4 moles of ethanol had been added to ethyl iodide, the fraction exchange reached 0·50 in 5 min, while without the addition of ethanol the exchange equilibrium was attained in 3 min. Moreover, within the next 25 min the fraction exchange remained practically constant. The 'exchange blocking' was also observed after adding small amounts of water, *n*-butyl amine or ether; in the first two cases a precipitate is produced, making the quantitative determinations impossible.

The fraction of the radioiodine atoms which do not participate in the exchange when the electron donor is

present in the solution ('retained activity') increases regularly with the value of the molar ratio [electron donor]: [AlI_3].

The 'exchange blocking' may be attributed to the well-known tendency of the trihalogenides of the aluminium group metals, which are distinct electron acceptors, to the formation of $D \rightarrow MX_3$ complexes, where D is the electron donor molecule[2]. The effect can be explained if one assumes that the exchange of iodine between the alkyl iodide and the $D \rightarrow MI_3$ complex is much slower than the exchange between alkyl iodide and metal iodide. Further investigations are needed to test this assumption.

We thank Prof. I. Zlotowski, head of the Department of Nuclear Chemistry, University of Warsaw, for many valuable comments.

Preparation of Aluminium Arsenide by a Vapour Phase Transport Reaction

Little work has been reported on the preparation of the semi-conducting compound aluminium arsenide, mainly because of the practical difficulties involved. Preparation from the melt is difficult because of the high melting point of the compound (about 1,700° C) and of the extreme reactivity of aluminium at this temperature. A few workers have prepared small crystals from the melt, and Stambaugh has produced polycrystalline ingots. This work is reviewed in ref. 1. The best of this material has an impurity carrier density of the order of $10^{19}/cm^3$ and is p-type.

We have prepared aluminium arsenide by an open-tube vapour phase transport method in which aluminium is transported in the presence of arsenic vapour in a stream of hydrogen. Aluminium is transported by the reversible reaction:

$$2\,Al + AlCl_3 \rightleftharpoons 3\,AlCl$$

in the temperature region 1,150°–1,000° C, and aluminium arsenide is formed either as free-growing crystals or as single crystal epitaxial layers on gallium arsenide substrates.

The material is transparent and orange brown in colour. It is not stable in moist air, quickly developing a 'bloom' on the surface, and slowly crumbling away, but good protection is afforded by dry hydrogen.

Epitaxial layers up to 200μ thick on substrates of 1 cm^2 area have been grown at rates of 0·4 μ/min. The substrate can be entirely removed by lapping and polishing with diamond paste under kerosene to leave a thin wafer of aluminium arsenide, to which electrical contacts may be made by soldering on gold wires with indium. Hall-effect measurements made on such wafers show them to be n-type with carrier densities of about $6 \times 10^{17}/cm^3$ and mobilities of about 100 cm^2/V-sec; compensation is suspected.

Spectrographic analysis has shown the major impurity to be silicon and improvements to the apparatus to eliminate sources of contamination are expected to yield material with a significantly lower carrier density.

Aluminium phosphide has also been prepared by a similar technique as an oriented growth on silicon substrates and as thin pale yellow needles. The conditions appear to be more critical than for the arsenide and growth rates have been very low.

We thank Mr. R. Greaves for his assistance and the management of these Laboratories for permission to publish this communication.

Characteristics of Benzylic Carbanions

The formation of a benzylic carbanion from 2-phenylethanethiol in the presence of potassium hydroxide at 200° ultimately yields polystyrene (53 per cent) by a β-elimination of sulphide ion[1]. Recently, we have observed that the carbanions formed from benzylsulphide and related species in potassium *tert*-butoxide/dimethylformamide (DMF) at 80° undergo a 1,3-re-arrangement and subsequent β-elimination of the sulphur moiety to yield stilbene[2] in the same manner as above. As a logical extension of these studies, we have examined the effect of the hetero atom on rearrangement-elimination reactions of this type. The results obtained are of theoretical rather than synthetic interest.

All decomposition studies were carried out in a 1 molar solution of potassium *tert*-butoxide in dimethylformamide at 80° for 20 h. The molar ratio of potassium *tert*-butoxide/reactant was three. The presence or absence of specific products was determined by infra-red, ultra-violet, and gas chromatography (temperature programmed on a 2-ft. silicone rubber column between 75 and 250°) comparison to authentic compounds. Under these conditions, dibenzyl ether gave only 3 per cent yield of stilbene despite the visual evidence of carbanion formation (deep red colour). Further, 1,2-diphenylethanol, 1-phenylethanol, and 2-benzyl-2-propanol did not form any measurable quantity of olefinic products. The latter can be attributed to an equilibrium reaction between *tert*-butoxide ion and the alcohol which leads to alkoxide ions and *tert*-butyl alcohol and to deactivation of the *tert*-butoxide ion by formation of alcohol-KO*t*Bu aggregates. In the former case, β-elimination would require formation:

$$t\,BuO^{\ominus} + RCH_2OH \rightleftharpoons RCH_2O^{\ominus} + t\,BuOH$$

of an oxide ion ($O^{(=)}$) which is highly unfavourable. Dibenzylamine behaved in a manner similar to dibenzylether and did not form any stilbene after 20 h. In contrast, 1,2-diphenylethyl-*N*-methyl amine afforded stilbene in 42 per cent yield and presumably methylamine. As previously noted, dibenzyl-sulphide readily undergoes a rearrangement-elimination to stilbene (45 per cent) and hydrogen sulphide in DMF.

When the foregoing results are considered all together one is led to several general conclusions under these reaction conditions. Elimination of sulphide ion proceeds much more readily than elimination of an oxide ion. β-elimination occurs in 1,2-diphenylethyl-*N*-methyl amine because of preferential proton abstraction from the 2-benzyl carbon atom and not from the amino group. Finally, the rearrangement of benzyl sulphide is facilitated not only by *d*-orbital stabilization of the initially formed carbanion (I) but also by the electron donor and accepting properties of:

I II

the sulphur atom[3] in the transition state for re-arrangement (II).

Although benzylic type ethers do not readily undergo rearrangement-elimination in DMF, it has been found that aralkyl ethers (ArOR) do β-eliminate to form olefines if a more active dipolar solvent is used[4]. In a 0·62 molar solution of potassium *tert*-butoxide/dimethylsulphoxide (DMSO) β-elimination of *n*-butyl phenyl ether and *n*-propyl phenyl ether occurred at 55°. For these experiments, 2,2-dimethylbutane was added as an internal standard and the olefinic products were identified by gas chromatography (21 ft. Dow Corning silicone oil on 'Chromasorb'). In the case of the *n*-propyl compound, a 24·5 per cent yield of propylene was observed after 169 h of reaction. The *n*-butyl derivative gave a 17·6 per cent yield of an equilibrium mixture of but-1-ene and *cis*- and *trans*-but-2-ene in the same reaction time. However, the leaving group in these ethers is a resonance stabilized phenoxide ion. Attempts to activate dialkyl ethers under these conditions was, as anticipated, not successful.

Preservation of Thin-layer Chromatograms

The preservation of chromatograms is one aspect of thin-layer chromatography which cannot be translated directly from the paper chromatographic technique. It is obviously impracticable to store the glass plates themselves and the answer to the problem lies in removing the completed thin-layer chromatogram from its glass support. Techniques have been described which rely on spraying the thin layer with suitable polymer dispersion, which hardens on drying to coat the layer with a clear film. The coating, plus the layer, is then removed mechanically from the glass plate. The method which is described here is an alternative means of preserving thin layer chromatograms which obviates the need for any spraying of the completed chromatogram and which is, in consequence, particularly useful for thin layers of a brittle nature.

In this method the chromatogram is removed from the glass plate by means of a self-adhesive plastic film. Films composed of cellulose acetate and PVC have been used in this connexion. ('Transpasene' and 'Transpaseal', manufactured by Dispro, Ltd., were used in this investigation.) The PVC film was more flexible and less porous than the cellulose acetate film and because of this was more useful for the preservation of chromatograms, which have a tendency to fade.

The completed thin layer chromatogram is placed face upwards on a flat surface. A sheet of plastic film is cut to a size which allows about 1-in. overlap around the edges of the glass plate. The backing paper is removed from the film and one edge of the film is turned under the glass plate and fixed in position. The film is then carefully smoothed over the thin layer working from the fixed edge. When in position over the layer, pressure is applied uniformly to the surface of the film using the edge of a ruler or a glass rod until there is a uniform dispersion of the particles of the adsorbent over the adhesive surface.

In this way the surface layer of the adsorbent particles, including the coloured zones, are transferred to the plastic film, which can then be peeled from the plate.

As a final step the plastic film is backed by a sheet of white card or paper of the same size as the original glass plate.

It has been found that using this procedure even amino-acid chromatograms, which fade readily, can be preserved in the absence of light for periods of several weeks provided the transfer of the thin layer to the plastic film is carried out immediately after completion of the chromatogram.

BIOPHYSICS

Preparation of Sieves with Microscopic Pore Diameters

Sieves with pore diameters in the micron range are finding increasingly frequent applications. While a number of commercially available articles fulfil criteria of pore size uniformity, these pathways are generally tortuous, with great individual variation in the exact hole pattern. A simple technique for preparation of such filters has therefore been developed.

A bundle of nylon monofilaments (kindly supplied by E. I. du Pont de Nemours and Co., Inc.) were oriented parallel to the long axis of a gelatin capsule mould, and embedded in butyl methacrylate polymerized at 60° C for 24 h. These blocks were then cut perpendicular to the fibres with a sliding microtome, and the sections floated in 37 per cent hydrochloric acid, dissolving the nylon.

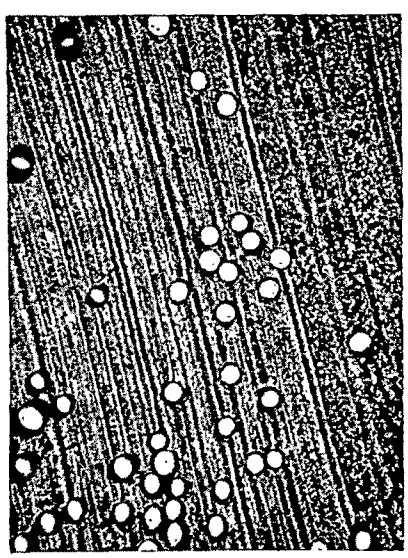

Fig. 1

The illustrated sieve in Fig. 1 has pores approximately 22μ diameter in a 40μ thick matrix. Orifice diameter/depth ratios as high as 1/10 are attainable with prolonged acid treatment, while the other specifications depend on choice of fibre, the mould used, and the microtomy technique. Serial sections are virtually identical, while the parallel orientation of the holes can be improved by keeping the fibres under tension during the embedding procedure.

Other fibre-embedding media combinations are now being investigated.

BIOCHEMISTRY

Origin of Norepinephrine in the Heart

NOREPINEPHRINE is present in various organs of the body and in the blood plasma[1]. The adrenal medulla is not necessary for the maintenance of tissue stores of this catecholamine[1], and it is likely that synthesis of norepinephrine occurs in the sympathetic nervous tissue throughout the body. Norepinephrine in the plasma originates from discharge of the neurohumour from the sympathetic nerve endings. The circulating catecholamine is excreted, metabolically inactivated (predominantly by *O*-methylation), or rebound in the tissues[2,3]. A portion of the norepinephrine present in each organ is derived from the circulating pool of catecholamine. The ability of the heart to take up, concentrate, and store intravenously administered norepinephrine has been amply demonstrated[4–6]. It has recently been shown that the isolated perfused heart is capable of synthesis of norepinephrine from tyrosine, at a sufficiently rapid rate to account for a considerable portion of the norepinephrine in this organ[7]. Thus norepinephrine stores in the heart could be maintained in part by extraction of the catecholamine from the circulation and in part by synthesis. We have used an isotope dilution technique to demonstrate that in the normal rat about 60 per cent of the norepinephrine present in the heart is synthesized in this organ, while the remainder is derived from the circulating pool of norepinephrine.

Male Sprague-Dawley rats, weighing 250–300 g, were placed in small restraining cages which allowed collection of urine during intravenous infusion through the tail vein. L-norepinephrine-8-^{14}C (130,000 c.p.m./μg) was infused slowly (0·896 μg/h) for 2, 6, 10, 24, 36, or 48 h. Groups of five to eight rats were used for each infusion period. Urine samples were collected during the 2-h interval before the end of the infusion. At the end of the infusion the animals were killed by a blow on the head and the hearts removed, weighed, and homogenized in 10 volumes of cold 0·4 N perchloric acid. The catecholamines were isolated from the clear supernatant of the tissue homogenates and from urine by absorption alumina and elution with 0·4 N perchloric acid[8]. Norepinephrine and epinephrine in the eluates were determined by a modification of the trihydroxyindole method[9]. Radioactivity present in 0·5 ml. of these eluates was estimated by liquid scintillation spectrometry[10]. The specific activity of the norepinephrine was calculated from the radioactivity and norepinephrine present in the alumina eluates. The ratio of the specific activity of norepinephrine isolated from the heart to that of the urinary catecholamine was determined.

Table 1. SPECIFIC ACTIVITY OF URINARY NOREPINEPHRINE-^{14}C

Time (h)	2	6	10	24	36	48
Specific activity (c.p.m./mμg)	32·0	60·0	62·0	63·6	52·6	59·4

L-Norepinephrine-8-^{14}C (130 c.p.m./mμg) was infused at a constant rate (0·896 μg/h). The specific activities shown are the means for the norepinephrine isolated from the urine of 5–8 animals at each time, collected during the 2-h interval prior to the indicated time.

After 6 h, the specific activity of the urinary norepinephrine was constant at about 60 c.p.m. ^{14}C/mμg norepinephrine (Table 1). This is considerably below the specific activity of the infused norepinephrine, indicating that the amount of norepinephrine being administered was largely diluted by endogenous norepinephrine and did not excessively increase the plasma catecholamine concentration. During the steady state that was established, the specific activity of the urinary norepinephrine may be assumed to be about the same as the plasma norepinephrine from which it is derived. If all the norepinephrine in the heart were derived from the plasma, then the specific activity of the catecholamine in this organ would be expected to increase until it became the same as the specific activity of the plasma (or urinary) norepinephrine.

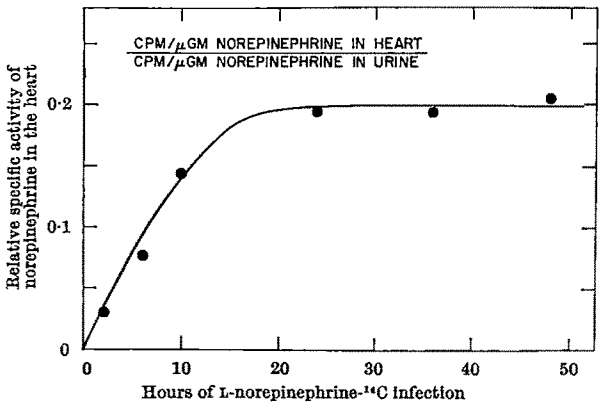

Fig. 1. Ratio of specific activity of norepinephrine in the heart and urine during a constant infusion of L-norepinephrine-8-^{14}C. Each point is the mean of this ratio for each of five to eight rats

If a portion of the norepinephrine in the heart were not derived from the plasma, but from synthesis, then the specific activity of the catecholamine in the heart would always be lower than the specific activity in the plasma (and urine). In the steady state, the ratio of the specific activity of the heart and plasma norepinephrine would be equal to the fraction of myocardial norepinephrine derived from the circulation. Fig. 1 shows the increase in the ratio of the specific activities of the myocardial and urinary norepinephrine. After one day of a constant slow infusion of L-norepinephrine-^{14}C the specific activity of the catecholamine in the heart remains at about 20 per cent of the specific activity of the urinary (and presumably plasma) norepinephrine. There was no increase in the myocardial norepinephrine concentration.

It can be concluded from these results that the myocardial stores of norepinephrine are maintained by both extraction of norepinephrine and by synthesis of catecholamine in the heart. About 80 per cent of the norepinephrine in the heart is synthesized in this organ (presumably within the sympathetic nervous tissue), while 20 per cent is derived from the circulating pool of norepinephrine.

A Mucoid isolated from Bovine Red Cells exhibiting Strong *Pneumococcus* Type XIV Cross-reactivity

IT is well known that all human and some animal red cells are agglutinated by anti-Type XIV pneumococcus serum[1–3]. The chemical nature of this phenomenon has been elucidated by Watkins and Morgan[4] by means of hæmagglutination inhibition tests and has been interpreted as being due to the presence of *O*-β-D-galactopyranosyl-(1->4)-*N*-acetyl-D-glucosamine in terminal non-reducing position. This structure is considered to be

an essential part of the human ABH— and Lewis blood group precursor substance, concluded from studies on the secreted material[5].

In the course of investigating the bovine erythrocyte mucoids, first described in 1958 by Klenk and Uhlenbruck[6], we have recently reported them to show blood group activity in the bovine system and to possess phytagglutinin receptors for the purified lectin from *Solanum tuberosum*[7,8]. Further investigations have led us now to the result that the neuraminic acid-free bovine erythrocyte mucoids also exhibit strong cross-reactivity with anti-Type XIV *Pneumococcus* serum. This was proved by precipitation tests, agar-gel diffusion and hæmagglutination inhibition tests. Such a finding was not unexpected, since the carbohydrate moiety of bovine erythrocyte mucoids is known to consist mainly of D-galactose and *N*-acetyl-D-glucosamine, besides *N*-glycolyl- and *N*-acetyl neuraminic acid[6,7].

According to the hypothesis of Bird[9], the receptors for anti-*Pneumococcus* Type XIV horse serum and for the lectin of *Ricinus communis* (as well as those of *Abrus precatorius*[10]) are very similar and probably identical in part. Therefore, it is noteworthy that we have found these bovine erythrocyte mucoids to react in nearly the same way also with the *Ricinus communis* lectin. Our experiments in fact confirm Bird's results.

The cross-reactivity of several other mucoids, such as x_1-seromucoid, secreted ABH-substances and mucoids from human red cells with the *Pneumococcus* Type XIV specific reagents will be presented in a detailed report, including chemical data on the multiple bovine erythrocyte mucoid receptors. Furthermore, most of these mucoids have been found to react also strongly with lectins from *Solanum tuberosum*, *Datura stramonii* and *Viscum album*, but in a slightly different manner. These observations are still under investigation.

We thank Dr. J. L. Hendry, New York State Department of Health, for supplying anti-*Pneumococcus* Type XIV horse serum, and Prof. W. T. J. Morgan, Lister Institute of Preventive Medicine (London), for testing some of our substances.

Sedimentation Constant–Molecular Weight Relation of Ribosomes

Roughly speaking, RNA of high molecular weight could be regarded as a polymer composed of nearly the same units as in the synthetic high polymer, if the minor differences in the structure of its base components are assumed to be negligible and hence the relation such as $[\eta]=KM^{\alpha}$ would be expected between its intrinsic viscosity $[\eta]$ and its molecular weight, M, which has been well known for the synthetic high polymers since the pioneer works of Staudinger. Indeed, Kurland[1] proved it on the ribosomal RNA, reporting that the value of α is nearly 0·5. Summarizing the data reported hitherto, Iso[2] also pointed out the following relation:

$$S_0=1{\cdot}4\times10^{-2}M^{0{\cdot}54} \qquad (1)$$

is applicable to the RNA of the high molecular weight, where S_0 is the sedimentation constant in Svedberg units and M the molecular weight. The value of the exponent in these formations is very close to those calculated theoretically on the model of spherical molecules of matted chains without free drain, a fact which provides us with an indirect support for the view of Hall and Doty[3] that RNA molecules could be regarded as an ellipsoid of revolution hydrodynamically.

These relations are available to estimate M of RNA from the measurements of S_0 or $[\eta]$ only and seem very useful from the practical point of view. But such a relationship has not yet been established for the ribosomal RNP. Using some data reported[4–9], therefore, we tried to find out an experimental formula available to the approximate estimation of its molecular weight as in RNA.

As shown in Fig. 1, a linear relationship between log S_0 and log M was found regardless of the source from which RNP was extracted. This linear relation can be expressed as follows:

$$S_0=0{\cdot}43\times10^{-2}M^{0{\cdot}65} \qquad (2)$$

As to the $[\eta]$, Ts'o stated already that it is independent of M. In fact, as shown in Fig. 2, its dependency on M is obscure, the measured points being scattered. As a rough approximation, the solid straight line was drawn in the figure, which is given by:

$$[\eta]=0{\cdot}28\times10^{-2}\,M^{0{\cdot}06} \qquad (3)$$

Both relations (2) and (3) suggest $S_0\alpha M^{2/3}$ and the independence of $[\eta]$ on M. If so, the ribosomal RNP molecules could be approximated, from the hydrodynamical point of view, by a compact, solid sphere.

Assuming that RNP is a compactly packed spherical molecule with a radius of R and a compactness of c, its M is given by $(4\pi/3)R^3\times c$ and hence we have:

$$[\eta]=\frac{5}{2}\cdot\frac{4\pi}{3}R^3\frac{N_A}{M}=2{\cdot}5\,N_A/c \qquad (4)$$

where N_A is the Avogadro number. Putting $c=14/(4\text{Å})^3$ in (4), we have $[\eta]=0{\cdot}068$, a value very close to those reported by Tissières *et al*[5]. When the frictional coefficient of RNP, ξ_0, is given by $6\pi\eta_0R$ (η_0 = the viscosity of the solvent), we have:

$$S_0=\frac{M(1-\rho\upsilon)}{N_A\xi_0}=\left(\frac{4\pi}{3}\right)^{1/3}\frac{M^{2/3}\,C^{1/3}\,(1-\rho\upsilon)}{6\pi\eta_0N_A} \qquad (5)$$

where υ is the partial specific volume of RNP, ρ the density of the media. Introducing the above value of c into equation (5), we obtain:

$$S_0=0{\cdot}69\times10^{-2}\,(1-\rho\upsilon)\,M^{2/3} \qquad (6)$$

Taking into account $\rho\sim1{\cdot}0$ and $\upsilon\sim0{\cdot}55$–$0{\cdot}60$, this relation is represented by the dashed line in Fig. 1, which is close to that obtained empirically.

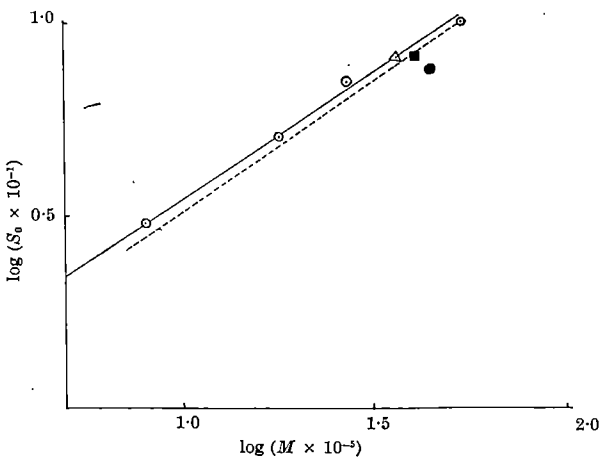

Fig. 1. ⊙, *E. coli* RNP (refs. 5 and 6); △, calf liver RNP (ref. 3); ■, yeast RNP (ref. 7); ●, pea seedling (refs. 4 and 8)

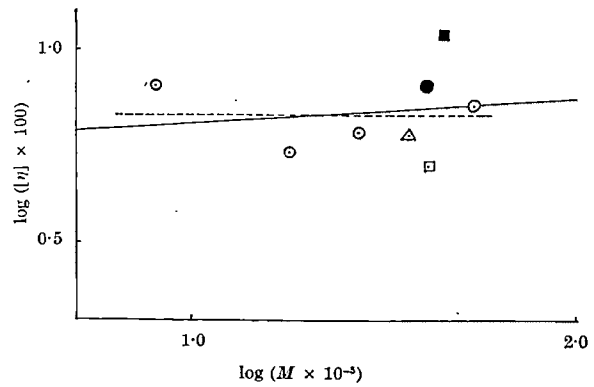

Fig. 2. ⊙, *E. coli* (refs. 5 and 6); □, yeast (ref. 7); △, calf liver (ref. 3); ■, pea seedling (refs. 4 and 8); ●, reticulocyte of rabbit (ref. 9)

The value of c assumed here means that, in the ribosome, an atom or an atomic group with the atomic weight of 14 (such as N or —CH_2—) is on an average contained in the volume of (4 Å)[3]. If the ribosomal particle were really a closely packed solid molecule as supposed from the electronmicroscopic observations, such a value of c would not seem so extraordinary or unreasonable. Thus it might be concluded that RNA should be compactly folded up in the ribosome, which is, in contrast to the isolated RNA, hydrodynamically approximated by a solid sphere, and the isolated RNA by a rigid spherical one composed of matted Gaussian chains or those similar to them, but without free drain. Moreover, the relations (2) or (6) would be available for estimating the approximate value of molecular weight of a ribosomal RNP by its ultracentrifugal data only as (1) with the isolated RNA.

Maltose in Red Clover (*Trifolium pratense*) Leaves

Traces of maltose in leaf extracts are generally attributed to amylase action on starch during processing of the samples and are avoided if enzymes are inactivated immediately after sampling. During investigations of diurnal fluctuations in red clover (*Trifolium pratense*) leaf carbohydrates, however, we have obtained the following evidence that free maltose is present in leaves collected at night.

Leaf samples (25 g wet wt.) collected at intervals over 24 h, during periods of sunny, summer weather (daybreak, 5–5.30 a.m.; darkness, 7.30–8 p.m.), were plunged immediately into boiling ethanol and processed to soluble sugar extracts[1]. Chromatograms of the extracts showed an easily detected reducing component, corresponding to maltose, in the night samples; this component was not detected in the day samples or in similar extracts of day or night samples of stems and petioles. The reducing disaccharide (20 mg), isolated by fractionation on charcoal-'Celite' of the extract from 100 g (wet wt.) of leaves collected at 1 a.m., was identified as maltose as follows. On chromatograms developed with a variety of solvents it had the same R_G as maltose and was clearly different from other diglucoses including cellobiose, while with diphenylamine-aniline it gave the blue colour typical of a 1–4 linked reducing aldohexose disaccharide[2]. The sugar also had $\alpha_D + 131°$ (maltose monohydrate, $\alpha_D + 130{\cdot}4°$), yielded glucose only on acid hydrolysis and gave an osazone with the characteristic crystalline form of maltosazone. The maltose-level in the leaves was measured by quantitative paper chromatography of the leaf extracts[3], using aniline hydrogen phosphate reagent, after first hydrolysing sucrose with an invertase which did not attack maltose. Similar results were obtained each time samples were collected; in a typical run the maltose (dry wt. basis) rose steadily from 30 mg per cent at 8 p.m. to 120 mg per cent at 5 a.m., after which it declined to an undetectable level by 7 a.m.

Enzyme extracts, prepared by grinding clover leaves in citrate buffer (0·1 M, *p*H 6·0), centrifuging and dialysing, were incubated with amylose and maltose respectively at various *p*H values and the digests analysed at intervals, by paper chromatography, for liberated sugars. Amylose digests showed a rapid release of maltose (*p*H optimum, 4·0–6·5) followed by a slower release of glucose, while the maltose digests showed a slow release of glucose (*p*H optimum 5·5–6·5). It is possible, therefore, that the maltose found in the leaves results from the different rates of activity of these two enzymes provided they are involved in the degradation of chloroplast starch at night[4]. Disappearance of maltose during the early hours of daylight may be due to continuing maltase action or to the use of the maltose as a primer in subsequent starch resynthesis.

Carbohydrases of the Rumen Oligotrich *Eremoplastron bovis*

From small-scale, pure cultures of several rumen oligotrichs, including *Eremoplastron bovis* (*Eudiplodinium neglectum*, Dogiel[1]), Hungate[2] prepared extracts containing cellulase and cellobiase. The extracts were not tested for other carbohydrases and appear to represent the only direct evidence for cellulolytic enzymes in rumen protozoa, apart from a recent observation of cellodextrinase in the extract from mixed *Entodinium* species[3]. Cultures of several oligotrich species were recently established[4] in this laboratory, enabling us to prepare 2–3 g (wet wt.) of cells of *Eremoplastron bovis* for a more detailed examination of its carbohydrases.

The *E. bovis* cells were collected from a clonal culture[4], freed from external bacteria, ground with Ballotini beads, diluted with water and centrifuged to yield extract *A* (10 ml.). The debris was extracted successively with citrate and phosphate buffers (0·1 M, *p*H 6·0 and 7·0 respectively) to yield extracts *B* and *C*. Extracts were dialysed, at 2° against water or buffer, and tested for carbohydrases in digests[3] which were incubated under toluene for 48 h and analysed at intervals for liberated sugars by paper chromatography. Extract *A* rapidly hydrolysed starch, xylans, xylodextrins and cellodextrins, hydrolysed maltose, xylobiose, cellobiose, laminaribiose,

sucrose and melibiose more slowly and was without action on various β-glucosides and β-galactosides, pectin and finely ground cellulose. Extracts *B* and *C* showed only weak amylase and xylanase activity.

As both amylose and β-limit dextrin were hydrolysed, at the same rate, to a similar mixture of end products (maltose plus smaller amounts of glucose and maltotriose) the amylase is probably an α-amylase. Xylans were hydrolysed by rapid removal of any arabinose followed by a slower, random hydrolysis of the xylan chain. Xylotriaose-pentose and wheat flour arabino-xylan were rapidly hydrolysed while insoluble xylan and clover hemicellulose were hydrolysed more slowly. Hydrolysis of cellodextrins was by the endwise removal of cellobiose. Cellotriaose was scarcely hydrolysed, but there was a rapid release of cellobiose from cello-tetraose and -pentaose and a slower release from long-chain, water-insoluble, cellodextrins[5]; in this latter case there was no sign of higher oligosaccharide intermediates.

The presence of amylase and xylanase in the extracts suggests that *E. bovis* can degrade plant polysaccharides other than cellulose. Although our extracts did not hydrolyse cellulose, including a sample of pebble-milled cellulose kindly supplied by Prof. Hungate, the presence in the extracts of cellodextrinase activity suggests that the organisms are able to degrade cellulose and that extraction of the entire complex of cellulolytic enzymes is more difficult.

Isolation of Alkaloids using Ultrasonic Energy

In recent years ultrasonic energy has been used in the extraction of various materials from plants, animals, and micro-organisms for biochemical analysis[1]. The application of ultrasound has proved advantageous for the isolation of enzymes, nucleic acids, and other heat-labile substances from cells and tissues. Moreover, ultrasonic energy has been used widely for various industrial applications to facilitate the extraction of commercially important substances[2]. The increasing use of ultrasonic instruments in extraction processes is based on the observations that: (1) disruption of cells is rapid; (2) the extraction process is accelerated; (3) the yield of extract usually is increased; (4) the use of ultrasonic energy permits the extraction of certain materials otherwise not readily obtainable.

While considerable attention has been devoted to explaining the mechanisms by which ultrasonic energy promotes the disruption of cells and aids in the extraction process, there is no generally accepted theory to account for the observed effects[3]. Many of the chemical, physical, and biological effects produced during ultrasonic treatment have been attributed to the activity accompanying gaseous cavitation, that is, the process of formation and collapse of cavities produced in an ultrasonically treated liquid due to successive rarefaction and compression. Though it is known that mechanical, thermal, chemical, and electrical energy is produced during cavitation[4], the part which each of these moieties of energy plays in cell disruption and subsequent extraction is not yet clear[3]. Nevertheless, in the specific reports where ultrasonic energy has been applied during the extraction process the results have been beneficial, and in many cases an increase in the amount of the extractable material was obtained or the extraction was completed in a much shorter time[5].

Our interest in increasing the yield of alkaloids obtained from *Datura stramonium* L. by various nutritional, cultural, and extracting procedures[6,7] led us to investigate the effectiveness of ultrasonic treatment when applied during the isolation of alkaloids. Previous workers have indicated the feasibility of this approach in the isolation of medicinal constituents from plants. But the technical refinements which we have introduced in the experiments briefly reported here have permitted us to evaluate this method further.

For the present work an extractor was designed which made it possible to carry out continuous extraction and at the same time expose the mixture of ground plant material and solvent to ultrasonic energy[7]. Utilizing this extractor it was possible to analyse separately the effect of ultrasonic treatment on the two processes, maceration and extraction, ordinarily involved in the isolation of alkaloids. The term extraction is used here to describe that process during the isolation of alkaloids in which the plant material is exposed repeatedly to fresh supplies of solvent. The term maceration implies swelling and soaking of the material without continuous recycling of the solvent. Frequencies of 20- or 40-kc/s ultrasound were obtained using two commercial ultrasonic generators and cleaning tanks. (Bendix Aviation Corp., model No. *UC–4X8*, 20-kc/s magnetostrictive unit, and Circo Ultrasonic Corp., Model No. *125T*, 40-kc/s piezoelectric unit.)

To determine the influence of ultrasonic energy when applied during the maceration process, each of a series of 10 g samples of ground *D. stramonium* leaf was placed in 300-ml. polyethylene containers and covered with a macerating solvent of 20 parts of ether, 12 parts of alcohol, and 8 parts of ammonia by volume. The containers were then immersed in the water of the ultrasonic tank and exposed for varying lengths of time to ultrasonic energy. To prevent vaporization of the solvent during this treatment, water-cooled reflux condensers were attached to the polyethylene containers and the temperature of the water in the ultrasonic tank was maintained continually at 24° C. After treatment, the samples were continually extracted with solvent for 3 h in Soxhlet extractors. All alkaloid determinations were made according to the U.S.P. assay procedure for *Belladonna* leaf[8]. Results of typical experiments illustrating the beneficial effect of 20- and 40-kc/s ultrasonic treatment during short maceration periods are shown in Table 1.

Table 1. Alkaloid Yield (mg/10 g Sample of *D. stramonium*) obtained after Short-term Ultrasonic Maceration of the Plant Material followed by 3 h of Conventional Extraction

Figures in parenthesis indicate percentage increase over control in recovery of alkaloids. Each determination represents the average value of not less than 3 assays

Treatment	Duration of ultrasonic maceration ½ h	1 h
Control	27·5	29·0
20 kc/s	30·0 (9%)	27·0 (0%)
40 kc/s	30·5 (10%)	31·5 (9%)

Samples of the ground plant to be used for ultrasonic extraction were treated in the same manner as described except that these samples were macerated in the conventional manner, without ultrasonic treatment. After a designated maceration period, each polyethylene container with macerating solvent was attached in turn to the new extractor, replacing the glass extraction flask, and placed in the water of the ultrasonic tank. In this manner it was possible to maintain the plant material in an ultrasonic environment throughout the duration of continuous extraction.

Our experiments indicate that short-term (2–4-h) conventional maceration followed by a 2-h period of ultrasonic extraction with the 20-kc/s generator results in significant increases in total alkaloids recovered when compared with

Table 2. Alkaloid Yield (mg/10 g Sample of *D. stramonium*) obtained after Conventional Maceration of the Plant Material followed by 2 h of Ultrasonic Extraction

Figures in parenthesis indicate percentage increase over control in recovery of alkaloids. Each determination represents the average value of not less than 3 assays.

Treatment	Duration of conventional maceration 2 h	4 h	8 h	24 h
Control	29·0	30·5	34·0	40·0
20 kc/s	32·0 (10%)	33·5 (10%)	36·6 (4%)	41·2 (3%)

control samples (Table 2). Similar experiments utilizing the 40-kc/s generator have demonstrated that increasing the frequency of ultrasound used during an extraction period of 1–2 h produces an increased yield of 15 per cent in total alkaloids recovered when compared to control samples.

The mechanical and thermal effects accompanying cavitation appear to be important in facilitating extraction by the use of ultrasound. Hydraulic shocks and intense stirring occurring at the cavitational points aid in increasing the interfacial surface between the solvent and the substrate by dispersing adhered and clumped particles, thereby making extraction more efficient. Localized stirring or 'acoustic streaming'[9] increases the diffusion rate of the desired material from the substrate and, consequently, decreases the diffusion gradient. Cavitation also causes adsorbed air on poorly wetted surfaces to be liberated, in this way increasing the area exposed to the solvent. Moreover, if cavitation is intense enough, disruption of the substrate particles occurs, increasing further the interfacial surface.

These results demonstrate that the application of ultrasound to the isolation of medicinal constituents from plants is advantageous in shortening considerably both the length of the maceration and the length of the extraction period. That this reduction in time is accompanied by efficient extraction without degradation of the active constituents or other unfavourable effects has been reported previously[10]. However, to our knowledge there has been no previous attempt to combine ultrasonic treatment with continuous solvent extraction. This technique should provide the means for further study to determine whether the same ultrasonic mechanism causes the increased yield of alkaloids observed during maceration and extraction. Our evidence suggests that during the maceration process the activity of ultrasound is to liberate alkaloids from bound sites within the cell and hasten their rate of diffusion into the solvent. During the extraction process it appears that ultrasound accelerates the physical separation of the alkaloids from the ground plant material.

PHYSIOLOGY

Sodium and Water Transport across Isolated Intestine of a Marine Teleost

The special osmo-regulatory mechanisms of the marine teleosts were originally outlined by Homer Smith[1]; he postulated that these animals maintain a constant blood concentration lower than that of the external sea-water by continual drinking of sea-water and simultaneous excretion of ions mainly through the gills. In addition to this and the work of Keys[2] on the common eel, several workers, Mullins[3] and House[4], have recently confirmed this theory of osmotic regulation by ion transport experiments *in vivo*. However, there have been no reported *in vitro* transport studies of the epithelial membranes involved in the regulation processes. The purpose of the investigation reported here was to determine the magnitude and direction of net transport of sodium and water, if any, across the small intestine of the marine teleost, *Cottus scorpius*.

Since there was no available information on the ionic concentrations in the blood of *Cottus*, we used *Lophius* Ringer (modified from Young[5]), which contained 205 mM NaCl, 8 mM KCl, 1·6 mM $CaCl_2$, 1 mM $MgCl_2$, 2·3 mM $NaHCO_3$, 0·5 mM KH_2PO_4 and 2·8 mM/l. glucose. The *p*H was 7·2. This Ringer was considered to be satisfactory because the tissue respired continuously in it for periods of at least 6 h. Respiration was followed in a Warburg apparatus, and the mean rate of oxygen consumption of six pieces of gut (3 animals) over a total of 35 h was $0·4 \pm 0·2$ µl. oxygen/mg dry weight/h at 25° C. In all the experiments recorded here the tissue was bathed on both sides by Ringer solution.

Net water transport was measured by the change of weight of normal and everted sacs, filled with Ringer, during 1 h incubation periods in Ringer, and also by a gravimetric chamber technique. The latter technique (to be described elsewhere) permitted simultaneous measurement of potential differences and short circuit current. In both these techniques the tissue was always equilibrated with Ringer for 1 h before commencing the hourly weight measurements. Observations of the net water flux (mucosal to serosal) across 22 pieces of small intestine from 16 fish gave a mean $\pm S.D.$ of $4·9 \pm 3·0$ µl./cm²/h (35 measurements). In four pieces of tissue exhibiting a net transport of water the movement was halted by the addition of 1 mM potassium cyanide to the serosal medium. This confirms the view that there is a net uptake of water across the intestine when no bulk osmotic driving force exists across the tissue and that this transport is dependent, at least indirectly, on the metabolism of the tissue.

The potential difference measured by silver–silver chloride electrodes for 9 pieces of small intestine was $0·0 \pm 0·5$ mV (mean $\pm$ *S.D.*). Since there exists no measurable potential difference across the tissue the magnitude of the fluxes of any ion in both directions determines whether there is active transport of the ion or not.

The serosal to mucosal sodium flux, ${}_SJ_M$, was found by immersing normal filled sacs in a continuously aerated ^{22}Na-loaded Ringer and monitoring the sacs in a well-type scintillation counter at known times after immersion. Before the counting procedure the sacs were washed by four rapid successive immersions in three separate volumes of Ringer; this washing technique was found to be tolerably efficient. Values of ${}_SJ_M$ (µequiv./cm²/h) were calculated from the familiar equations for a two-compartment system. The sacs were then transferred to a large volume of aerated Ringer, and values of mucosal to serosal sodium flux, ${}_MJ_S$, were found from the decrease in specific activity of the sacs with time. A few representative values of ${}_SJ_M$ and ${}_MJ_S$ in the same sacs are shown in Table 1.

It is clear from the results that there is an active transport of sodium, ${}_MJ_S^{act.}$, from mucosal to serosal surfaces of the isolated intestine of *Cottus*. However, as the

Table 1

Sac No.	Sodium fluxes (μequiv./cm²/h) $_{S}J_{M}$	$_{M}J_{S}$	$_{M}J_{S}^{net}$
1	13	30	17
3	15	21	6
6	13	23	10
9	15	25	10
Mean ± *S.D.* (9 sacs)	14 ± 3	28 ± 5	12 ± 4

potential difference measured was zero there must be either net anion transport in the direction of active sodium movement or net cation transport from serosal to mucosal surfaces. The interesting question of whether there is active anion transport or not remains to be investigated.

The work recorded here tends to support previous *in vivo* measurements on ion absorption by marine teleosts, as it appears that sodium and perhaps chloride are transported actively by the intestine. Schoeffeniels[6] has shown that there are permeability differences between separate regions of the turtle intestine, and similar studies on marine teleosts would lead to a better understanding of ionic regulation in this group.

Transient Responses of Purkinje Fibres to Non-uniform Currents

Comparisons between experimentally recorded responses of cardiac muscle to applied currents[1–3] and responses predicted by a modified form of the Hodgkin–Huxley nerve equations[4] have led to conflicting conclusions about the applicability of these equations to the cardiac cell membrane[2,4,5]. The existence of a negative membrane conductance in the equations means that strong enough inward currents applied uniformly to the membrane during the plateau of the action potential should initiate an all-or-nothing repolarization response. Fig. 1 shows computed responses to uniform currents.

However, the experimental records at present available

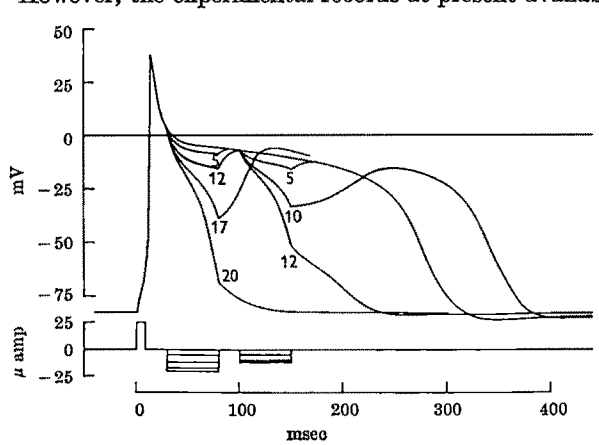

Fig. 1. Computed responses of Purkinje fibre to uniform currents. Current strengths and durations are indicated by current plot at bottom of illustration and by the figures (in μamp/cm²) on the potential curves (Noble, D., ref. 6)

were obtained by applying currents non-uniformly from one point in cable-like preparations[3] or sheet-like preparations[2]. Fig. 2 shows the effects of currents applied at one point in cable-like preparations (mammalian Purkinje fibres). It can be seen that there are large differences between these responses and those shown in Fig. 1. The voltage threshold is beyond the resting potential and little or no inflexion is observed until the current pulse is terminated. The larger sub-threshold responses are followed by a break re-excitation.

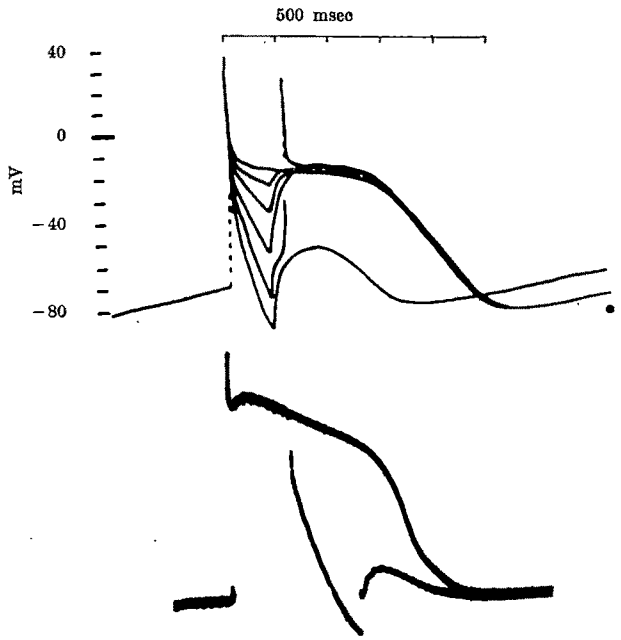

Fig. 2. Experimentally recorded responses of Purkinje fibres to currents applied at one point. Top, from Weidmann, S. (ref. 3); bottom, from Hoffman, B. F., and Cranefield, P. F. (ref. 1)

Recent computations of the steady-state behaviour of the equations for non-uniform polarization have shown that the experimental results do not necessarily conflict with the theory[6]. We have now computed transient responses to currents applied at one point in a cable-like preparation. The equation for this situation is:

$$\frac{a}{2R_i}\frac{\partial^2 E_m}{\partial x^2} = C_m\frac{\partial E_m}{\partial t} + g_{Na}(E_m - E_{Na}) + g_K(E_m - E_K)$$

where a = radius of fibre (38μ), R_i = intracellular fluid resistance (105 ohms/cm), C_m = membrane capacity (12 μF/cm²), E_m = membrane potential (mV), E_{Na} = sodium equilibrium potential (40 mV), E_K = potassium equilibrium potential (−100 mV), g_{Na} = sodium conductance (mmho/cm²), g_K = potassium conductance (mmho/cm²), x = distance along fibre (cm) and t = time (msec). The equations for g_{Na} and g_K are those used to reproduce the Purkinje fibre action potential[4].

Fig. 3 shows computed responses at $x = 0$ to square wave currents of various amplitudes applied between 100 and 200 msec after the initiation of an action potential. It can be seen that these responses resemble the experimental records very much more closely than those in Fig. 1. The voltage threshold for initiating the all-or-nothing termination of the plateau is beyond the resting potential and is considerably more negative than the computed steady-state threshold at 200 msec[6]. Currents which re-polarize the membrane beyond about −60 mV and which fail to terminate the plateau are followed by a break re-excitation and, as in experimental records, the spike is preceded by a delay. This effect was not reproducible in the computed responses to uniform currents (Fig. 1) since the membrane could not be repolarized sufficiently to reactivate the sodium-carrying system without terminating the plateau.

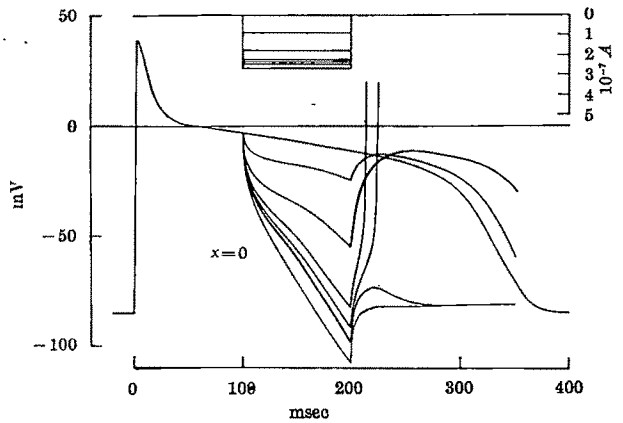

Fig. 3. Computed responses of Purkinje fibre to currents applied at one point between 100 msec and 200 msec after initiation of an action potential. Fibre-length, 6·25 mm; fibre-diameter, 75μ; resting space constant $\simeq$ 2 mm. The heights of the spikes following the strongest sub-threshold currents are uncertain

These results show that the theory is capable of reproducing some of the features of the transient responses to non-uniform currents.

We thank Prof. A. F. Huxley for allowing us to use his formula for numerical integration. This was used together with the Crank–Nicolson method[7,8] modified to apply to non-linear partial differential equations. The numerical computation was done on the Ferranti *Atlas* computer at the University of Manchester.

Substance *P* Content and Effect on Capillary Permeability of Extract of Various Parts of Human Brain

Chemically pure substance *P*, apart from causing vasodilatation and stimulation of smooth muscle[1], also increases capillary permeability[2]. We have now tested extracts of four parts of human brain, containing different amounts of substance *P*, for their effectiveness in increasing capillary permeability. The effects on the guinea pig ileum of acid-boiled extracts of substantia nigra, basal ganglia, cortex and cerebellum were compared with the effect of a standard preparation of substance *P* made from bovine intestine (for methods, see ref. 3). The results are listed in Table 1, col. 3. For estimating the effects of the brain extracts on capillary permeability, other vasoactive substances (acetyl choline, adrenergic amines, histamine, serotonin, ATP, ADP and AMP) had to be removed so far as possible; this was done by successive precipitations with ammonium sulphate and acetic acid-ether. The resulting 'purified extracts' were tested for activity in increasing capillary permeability of rabbit skin, using a modification of the method of Frimmer and Müller[4].

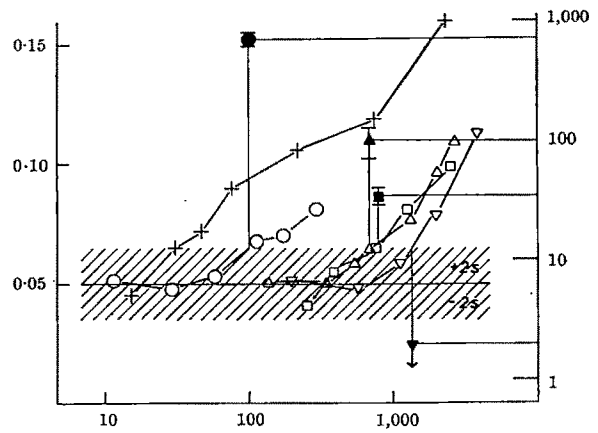

Fig. 1. +, Substance *P* standard (13·2 units/mg, made from bovine intestine); ○, substantia nigra; △, basal ganglia; □, cortex; ▽, cerebellum. Abscissa, μg of purified extract injected intradermally. Left ordinate, extinction of dye solution extracted from blued skin areas. Full symbols show the relation between the amounts of purified extracts producing +2s increase of capillary permeability and the amount of substance *P* (right ordinate (μ/g)) in the respective brain area

The amounts of 'purified extracts' of the different parts of the brain which caused a significant increase (+2s) in capillary permeability differed considerably (Table 1, col. 7); for example, 0·1 mg of extract of substantia nigra containing 719 units substance *P*/g, compared with 1·3 mg of extract of cerebellum containing less than 2 units substance *P*/g. With regard to the corresponding amounts of tissue the differences were still more pronounced (Table 1, col. 9); e.g., extract corresponding to 41·5 mg of substantia nigra produced the same increase in capillary permeability as extract corresponding to nearly 17 times more cerebellum.

'Purified extracts' with equal activity in increasing permeability contained different amounts of substance *P*; for example, 18·8 units for substantia nigra and less than 0·1 unit for cerebellum (Table 1, col. 8). This can be explained by assuming that even the 'purified extracts' contained, apart from substance *P*, other material capable of increasing capillary permeability. This became apparent especially when larger quantities of the 'purified extracts' had to be injected.

Fig. 1 shows the dose-response curves of the four 'purified extracts' and their permeability-increasing activities. The +2s increase in capillary permeability is compared with the substance *P* content of the same brain area: there is a clear correlation between them.

Table 1

1	2	3	4	5	6	7	8	9
	Dried extract mg/g tissue	Substance *P* units/g tissue	Purified extract mg/g tissue	Units of substance *P*/mg purified extract	Recovery of substance *P* in purified extracts (%)	Increase in capillary permeability of (+2s) produced by: μg purified extract	= Corresponding units of substance *P*	= Corresponding mg of wet tissue
Substantia nigra	58	719 ± 82	2·4	188·0	60·8	100·0	18·8	41·5
Basal ganglia	53	102 ± 33	2·4	19·0	51·1	680·0	12·9	282·0
Cortex	60	34 ± 6	2·6	9·0	60·7	800·0	7·2	308·0
Cerebellum	60	2·0	1·9	< 0·1		1·300	< 0·1	685·0

This indicates that less than 50 mg substantia nigra contain enough substance *P* to produce quite a pronounced increase in capillary permeability.

It is possible, therefore, that substance *P* enables those parts of the brain which are rich in it to have particularly high rates of exchange, either potential or permanent, between the capillaries and the surrounding tissue.

Reduction by Chlorpromazine of Pylorus-ligation Ulcers in the Rat

Recent research indicates that chlorpromazine is an effective inhibitor of gastric secretion[1-3] and reduces starvation ulcers in mice[4]. This investigation was undertaken to determine quantitatively the extent of ulceration in the fore-stomach and glandular stomach of the pylorus-ligated rat after treatment with chlorpromazine.

Twenty-eight adult, male and female albino rats (Holtzman strain) were involved in the investigation. Each rat was separately caged and water was accessible *ad libitum* to all rats for a 24-h pre-operative fasting period. The Shay rat procedure[5] of duodenal ligation was performed under ether anæsthesia. Three subcutaneous injections (inguinal region) were given post-operatively at 8-h intervals to all rats. Treatments consisted of the following injections: 5·0 mg chlorpromazine/kg bodyweight (Thorazine, Smith, Kline, and French Lab., about 0·06 c.c.); 2·5 mg chlorpromazine/kg (approx. 0·03 c.c.); or 0·06 c.c. water (control animals). The number of rats per treatment is indicated in Table 1. Drinking water was removed subsequent to the surgical procedures. Twenty-four h after pyloric ligation the stomachs were removed, opened along the lesser curvature, and both the fore-stomach and glandular region of each stomach were evaluated for gastric pathology by the ulcer index developed by Pfeiffer and Gass[6], which has a minimum rating of 1 (normal stomach) and a maximum rating of 15 (highly ulcerated stomach).

Table 1. Ulcer Reduction by Chlorpromazine in the Pylorus-ligated Rat

Treatment*	No. of animals	Mean weight at surgery (g)	Mean ulcer index ± *S.E.* (fore-stomach)	Mean ulcer index ± *S.E.* (glandular region)
Water (control) 0·06 c.c.	10 (5 ♂, 5 ♀)	337	10·8 ± 1·5	7·2 ± 0·2
Chlorpromazine 2·5 mg/kg 0·03 c.c.	8 (6 ♂, 2 ♀)	362	4·2 ± 2·0	3·2 ± 1·0
Chlorpromazine 5·0 mg/kg 0·06 c.c.	10 (4 ♂, 6 ♀)	336	2·9 ± 1·4	2·9 ± 1·0

* All injections subcutaneous (inguinal region) t.i.d. at 8-h intervals for 24 h.

The results of the investigation are illustrated in Table 1. The mean fore-stomach ulcer index was higher than the mean glandular stomach ulcer index except in the 5·0 mg/kg group where the indices were equal. Greater ulceration of the fore-stomach of pylorus-ligated rats is a phenomenon commonly reported by earlier investigators[6]. Ulceration of both regions of the stomach was graded from severe ulceration in the control group to greatly minimized ulceration in the 5·0 mg/kg group. The protective action of the higher dose of chlorpromazine was only slightly greater than that of the lower dose.

It can be concluded that chlorpromazine minimizes ulceration in the Shay rat. This reduction of ulceration is similar to the protective action afforded by bilateral vagotomy in the pylorus-ligated rat[7]. The present investigation quantitatively confirms past findings that chlorpromazine reduces ulcers in the Shay rat[8,9], supposedly by inhibition of gastric secretion[1-3]. By means of an ulcer index, the protective effect of chlorpromazine on both the fore-stomach and the glandular stomach has been evaluated.

This investigation was supported in part by a U.S. Public Health Service research grant, No. *A*–5560, from the Division of Pharmacology and Experimental Therapeutics, National Institutes of Health, and in part by a grant from the National Science Foundation, No. *GE*–939.

ANATOMY

Centrifugal Fibres in the Lateral Olfactory Tract

For the interpretation of results of electrophysiological studies of the responses in the olfactory bulb to stimulation of the lateral olfactory tract it is a matter of some importance to know whether this tract consists solely of efferent fibres from the bulb or whether it also contains centrifugal fibres to the bulb[1-3]. Such centrifugal fibres were described by Cajal[4], who, although uncertain of their origin, clearly distinguished them from those in the anterior commissure (which, coming from the opposite olfactory bulb, should be considered as commissural). The commissural fibres have been demonstrated experimentally by several workers; but with one exception[5] the presence of centrifugal fibres in the lateral olfactory tract has been either denied or overlooked. However, as all reports agree that after interruption of both the anterior limb of the anterior commissure and the lateral olfactory tract the degeneration is heavier in the ipsilateral than in the contralateral olfactory bulb[5-7], it is clear that a proportion of the fibres to the bulb must be arising in the ipsilateral hemisphere, but it is not known to what extent these run in the lateral olfactory tract or in the anterior commissure. In order to determine if centrifugal fibres run in the lateral olfactory tract it is necessary to place lesions which are strictly limited to the tract.

Following such lesions in the rat heavy fibre degeneration has been found, in Nauta preparations, passing forwards in and along the deep aspect of the tract to the ipsilateral olfactory bulb. In the main bulb severe fibre fragmentation is seen in the periventricular and granule cell layers; but in addition a considerable number of degenerating fibres pass beyond the mitral cell layer to the external plexiform layer, many reaching as far as the glomeruli. Although no degeneration is seen within the glomeruli themselves, the terminal degeneration on the

periglomerular cells clearly outlines them. In the granule cell layer of the accessory olfactory bulb there is some fibre fragmentation, but no degeneration could be traced with certainty beyond the mitral cells; there was no degeneration in either the main or the accessory olfactory bulbs of the opposite side. Following a 'leucotomy'-type lesion just caudal to the frontal pole with complete interruption of both the anterior limb of the anterior commissure and the lateral olfactory tract[5] the fibre degeneration in the periventricular and granule cell layers of the ipsilateral olfactory bulb is very much denser than after section of the tract alone, but the amount of degeneration seen in the external plexiform layer and around the glomeruli is no greater. In the contralateral olfactory bulb there is moderately severe fibre degeneration in the periventricular and granule cell layers, but in the external plexiform layer only a very occasional degenerating fibre is seen, and there is no degeneration around the glomeruli. In the granule cell layers of the accessory olfactory bulb of both sides a little fibre degeneration is found.

The exact site of origin of the centrifugal fibres which run in the lateral olfactory tract must await further research, but from the material available the amygdala and the adjacent part of the pyriform cortex, together with the hypothalamus and the preoptic areas caudal to the olfactory tubercle, can be excluded. On the other hand, all experiments in which the olfactory tubercle has been damaged have resulted in degeneration of the coarse centrifugal fibres running with the lateral olfactory tract; but as lesions of the rostral part of the pyriform cortex inevitably involve the tract itself a contribution from this area cannot be eliminated. It would be of interest to determine in future experiments whether the olfactory tubercle is the major source of centrifugal fibres, and also whether these fibres arise from the antero-lateral part of the tubercle which receives direct afferents from the olfactory bulb, or from the larger posteromedial part which is related to the olfactory bulb indirectly by way of the pyriform cortex. The conclusive demonstration of the olfactory tubercle as the principal site of origin of the centrifugal fibres to the bulb would mean that in the olfactory system there is provision for the reflex control of activity in the bulb (comparable to that of the γ efferent system in the spinal cord[3] and the feed-back loop in the avian visual pathway[2]) and, at the same time, for a possible influence by the brain-stem reticular formation by way of the ascending fibres in the medial forebrain bundle. The finding that the centrifugal fibres in the lateral olfactory tract terminate in relation to the periglomerular cells as well as with the granule cells indicates that the centrifugal control of olfaction may operate at the level of both the first- and second-order neurones, as well as interacting with the commissural fibres from the olfactory bulb of the opposite side.

HÆMATOLOGY

Occurrence of Hæmoglobin H in Leukæmia

Appreciable proportions of fœtal hæmoglobin (Hb–F; $\alpha_2^A\gamma_2^F$) have been found[1,2] in occasional cases of childhood leukæmia. This hæmoglobin has also been detected in some adult leukæmias[3]. Among the adult cases of erythroleukæmia examined by us[4], three were exceptional in showing red-cell inclusion bodies after supravital staining, associated with the presence of a minor hæmoglobin component with electrophoretic properties very similar to those of Hb–H (Hb–β_4^A).

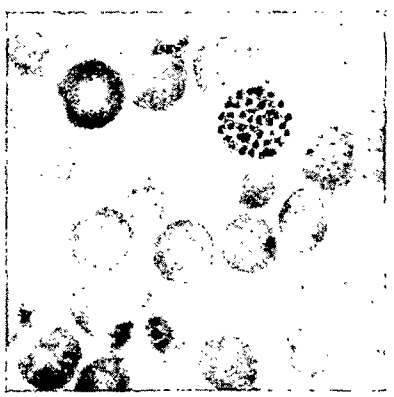

Fig. 1. Photomicrograph of blood film, spread after incubation with brilliant cresyl blue supravital stain, showing some red cells containing inclusion bodies (× 1,750)

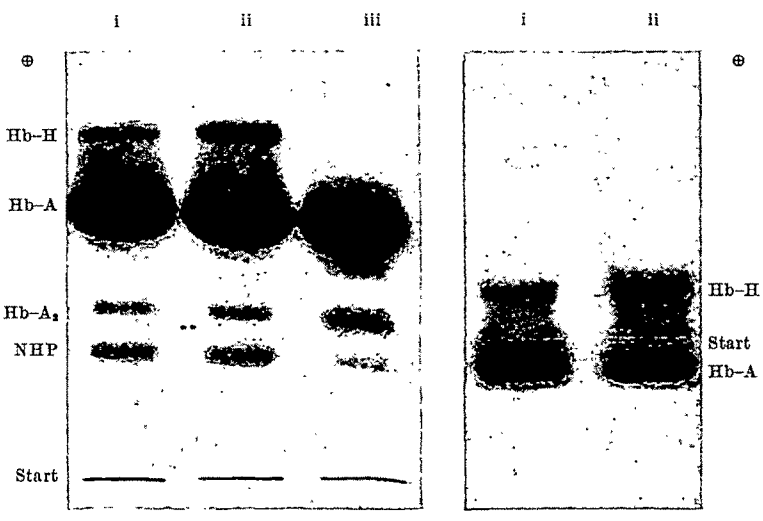

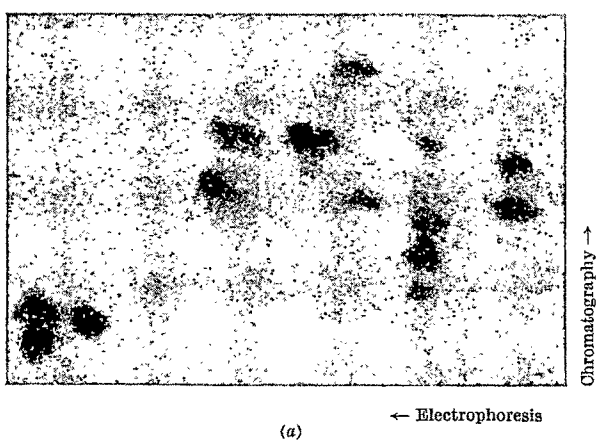

Fig. 2. Starch-gel electrophoretic analyses of hæmolysates. (*a*) *p*H 8·6 *tris*/borate discontinuous buffer system: (i) patient, (ii) Hb–H trait, (iii) normal adult (NHP denotes non-hæm protein); (*b*) *p*H 6·9 phosphate buffer: (i) patient, (ii) Hb–H trait. Stained with naphthalene black

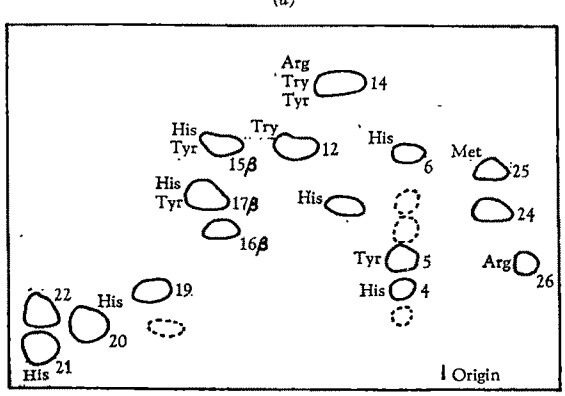

A case of atypical chronic myeloid leukæmia in a 56-year old male of known British descent has now been found which exhibits similar red-cell inclusion bodies (Fig. 1), associated with the presence of about 10 per cent of a minor hæmoglobin, with no detectable proportions of Hb–F and Hb–Bart's (Hb–γ_4^F) and no alteration in the level of the normal minor hæmoglobin Hb–A_2($\alpha_2^A\delta_2^{A_2}$). The abnormal hæmoglobin has now been identified as Hb–H by direct comparison (Fig. 2) with authentic Hb–H by starch-gel electrophoresis at *p*H 8·6 and *p*H 6·9; the latter *p*H, using a phosphate buffer, is particularly suitable[5] for the detection of Hb–H and Hb–Bart's which have anodic mobilities under these conditions, in contrast to Hb–A

Fig. 3. Separation of abnormal hæmoglobin by starch-block electrophoresis of patient's hæmolysate; *p*H 8·6, barbitone buffer, ionic strength 0·05

(*a*)

(*b*)

Fig. 4. Photograph and tracing of 'finger-print' of abnormal hæmoglobin. Electrophoresis in pyridine–acetic acid buffer, *p*H 6·4, 75 min at 40 V/cm; ascending chromatography with pyridine/iso-amyl alcohol/water (35 : 35 : 27) overnight; stained with ninhydrin

which moves toward the cathode. The abnormal component was readily separated from Hb–A by electrophoresis on starch block at *p*H 8·6 (Fig. 3), and examined by the 'finger-print' method, after removal of the hæm, using a modification of the procedures of Ingram[6] and Baglioni[7]. The locations of the arginine, methionine, histidine, tryptophan and tyrosine residues in the separated peptide spots were found by using the specific staining reagents described by Smith[8]. All the peptides, namely, Nos. 3, 9, 10, 11, 13, 15α, 16α, 17α, 18 and 23 arising solely from the α^A chain (numbering system of Baglioni[7]), were absent. The remaining peptides corresponded in both position and specific staining reactions to those expected for a normal β^A chain (Fig. 4).

The parents of the patient were not available for study, but his daughter was hæmatologically normal with no indications of abnormal hæmoglobins or of thalassæmia. There was no history suggestive of any hæmatological abnormality in the patient prior to the onset of the present leukæmic illness. The formation of Hb–H may well be an acquired process associated with the leukæmic state, as seemed possible in the cases of erythroleukæmia studied previously[4].

A possible explanation for the presence of Hb–H is that the leukæmic state sometimes leads to an imbalance of hæmoglobin chain synthesis, resulting in a relative excess of β^A chains which combine to form Hb–H, as in the case of α-thalassæmia[5]. The absence of Hb–F and Hb–Bart's in this subject precludes the compensatory production of γ^F chains, though this appears to be a feature of some childhood leukæmias[1,2]. A disturbance of the balance of hæmoglobin chain synthesis of this nature does not necessarily imply the operation of genetic factors, such as those discussed by Shuster *et al.*[2], though this possibility cannot be excluded at the present time.

We thank Prof. J. V. Dacie for the opportunity to examine this case and Dr. H. Lehmann for a reference hæmolysate containing Hb–H.

PHARMACOLOGY

Thyroid-adrenocortical Antagonism and Histamine Metabolism

Bjurö, Westling and Wetterqvist[1] have recently suggested that there is a direct antagonism between the actions of the adreno-corticosteroids and those of the thyroid hormones on histamine metabolism in rats. Their results were obtained, chiefly, by estimating the urinary output of histamine. We have been investigating this problem over the past two years[2,3] and conclude that this action of the thyroid hormones is mediated indirectly through their effects on the level of adrenocorticosteroids in the body. Thus only the glucocorticosteroids exert a direct effect on histamine metabolism, their blood concentrations determining the level of histamine sensitivity and of other aspects of histamine metabolism.

We have administered thyroxine sodium (1 or 2 mg/kg daily) to groups of rat and mice and then tested them for sensitivity to histamine. In all experiments, a temporary increase in sensitivity to histamine was noted, coupled with elevated tissue and urinary histamine. Continued treatment with thyroxine beyond 14 daily doses in rats, however, tended to reduce the increased sensitivity to

histamine, and adrenal cortical hypertrophy resulted. A similar temporary increase in sensitivity to histamine was observed in mice but thyroxine treatment beyond 8 days caused a return to normal sensitivity and a marked adrenal hypertrophy. On the other hand, hypothyroid animals showed a depressed sensitivity to histamine which again was only temporary, and continued treatment with antithyroid drugs tended to reduce the depressed sensitivity to histamine and adrenal cortical atrophy resulted. It appears, therefore, that a prolonged change in thyroid hormone-levels leads to a compensatory change in adrenocortical secretion which may be responsible for the return of histamine sensitivity to control-levels. Further experiments showed that simultaneous administration of a glucocorticosteroid prevented the thyroxine-induced increase in histamine sensitivity; instead, a histamine-resistant animal was produced. When hypothyroid animals were adrenalectomized, a marked increase in histamine sensitivity was found instead of a decrease usually observed in hypothyroid animals. Thus, irrespective of the thyroid state, the level of circulating corticosteroid in the body determines the level of histamine sensitivity, and this is represented diagrammatically in Fig. 1 where the sensitivity to histamine and histamine releasers in various hormonal states is indicated.

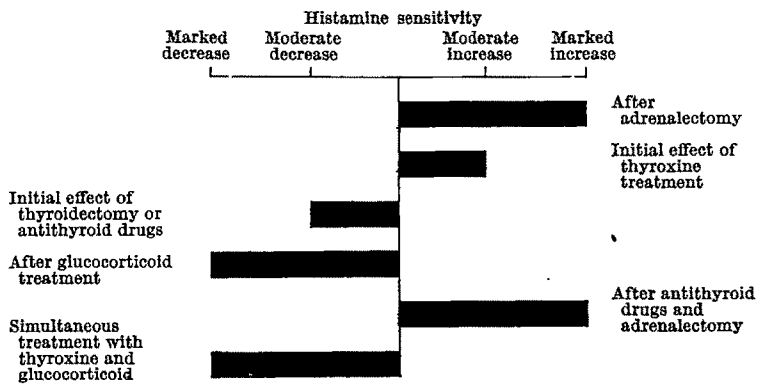

Fig. 1. Sensitivity of rats and mice to injections of histamine and of histamine releasers in various hormonal states

The rate of disappearance of corticosteroid from the plasma has already been shown to be accelerated in thyrotoxicosis[4], the steroids being metabolized at a faster rate[5], and we suggest that the histamine-sensitizing effects of thyroxine treatment are brought about by a reduction in tissue levels of corticosteroid. The internal compensatory mechanism stated here consists of a marked increase in endogenous glucocorticosteroid secretion from the adrenal cortex, after stimulation from the pituitary gland, becoming effective after prolonged thyroxine treatment. The initial effect of a hypothyroid state can be explained on a similar basis: there is a reduction in the rate of steroid metabolism and an accumulation of glucocorticosteroid in the tissues, leading to a depressed histamine sensitivity. Adrenal cortical atrophy follows and histamine sensitivity returns to control-levels. Thus there is antagonism between the adrenal cortex and the thyroid secretion, but the adrenal cortex appears to be the more important factor as regards a direct action on histamine metabolism.

PATHOLOGY

Rapid Liver Tumour Induction by Concerted Action of *N*-Hydroxy-2-acetamidofluorene and Hormonal Stimulation

Liver is not usually considered a target organ of hormonal factors known at present. Nevertheless, in certain animal species, the operation of such agents is clearly evident. Thus, liver cancer induction by certain carcinogenic azo dyes occurs more readily in female than in male mice. With certain other azo dyes[1], and with 2-acetamidofluorene[2] and its probable proximate agent *N*-hydroxy-2-acetamidofluorene[3], male rats are considerably more susceptible than females. Liver carcinogenesis is enhanced by the joint administration of anabolic hormones, testosterone or cortisone, and 2-acetamidofluorene, its diacetyl derivative[4] or its *N*-hydroxy derivative[5]. Castration of female rats and joint administration of testosterone and 2-diacetamidofluorene gave rise to liver tumours to almost the same extent as in male rats[6]. Whether these hormonal factors act directly or by way of alteration of the total hormonal balance involving the pituitary, gonads, adrenals and target organ is, at present, not known. Surgical removal of the adrenals or of the pituitary gland delays or abolishes carcinogenesis in the liver by azo dye or the carcinogenic fluorene derivatives (see ref. 7). Participation of hormonal factors derived from the pituitary in the carcinogenic process in the liver might therefore be surmised. However, direct evidence on this point has so far not been adduced. Bielschowsky[8], Laws[9], and also Glinos *et al.*[10], have attempted to devise experiments to establish a multiple stage mechanism for liver carcinogenesis, but their observations were either negative or at best suggestive for the operation of such a process.

Furth *et al.*[11], making use of the functional pituitary tumours produced by them, have demonstrated the essential promoting action of hormones elaborated by the transplantable tumour in the induction of primary mammary gland tumours in rats or mice treated with a single dose of a carcinogenic hydrocarbon, of radiation or of a viral preparation. We have now applied this type of approach to the successful demonstration of a concerted action between pituitary hormonal factors and low doses of *N*-hydroxy-2-acetamidofluorene in regard to liver cancer induction in male and female rats.

Weanling, four-week-old male and female Fischer strain (*F*344/*N*) rats were divided into four groups (Table 1). Group 1 consisted of untreated controls fed a semi-synthetic 18 per cent casein diet with adequate micro- and macro-nutrients (diet *A*). Group 2 was fed a diet containing 0·016 per cent *N*-hydroxy-2-acetamidofluorene in an otherwise identical diet (diet *K*). Animals in Group 3 were fed control diet *A* and received a subcutaneous implant of the Furth mammotropic tumour *MtT*/*F*4 in the back. Group 4 was administered carcinogenic diet *K* and received implants of the mammotropic tumour. This transplantable pituitary tumour served as a source of ACTH, growth hormone and prolactin[12].

The implanted mammotropic tumours in Groups 3 and 4 were first palpable in about 6 weeks and grew progressively to a large size in the subsequent 7 weeks. Animals in all experimental groups were killed at the end of 13 weeks.

The livers of all control animals, Group 1, were perfectly normal. The expected response was found in Group 2. The male rats had livers weighing twice as much as compared with the control animals. Six out of the 7 were grossly nodular. Microscopically, small nodules of hepa-

toma along with cirrhotic changes were seen in the livers of all the males and to almost the same extent in the females. In four of the females, however, the hyperplastic nodules were only seen at the microscopic level. In the *MtT* control Group 3, the livers of both male and female animals were enlarged about equally as was evidenced by the hypertrophic aspect at the microscopic level. Furthermore, as reported[13,14], the kidneys of both sexes were 4–5 times larger than those of the control groups. In Group 4, namely, the animals receiving carcinogen and mammotropic tumour, the livers were enlarged in all and most of them were nodular. Compared with the findings in Group 2 on carcinogen alone, the lesions of both male and female animals were similar and extensive. Hepatocellular carcinoma—either trabecular or adenomatoid type—were seen in livers in these groups. Renal hyperplasia was much less extensive in Group 4 than in Group 3.

Thus the combined action of the hormonal stimulus and chemical carcinogen gave rise to advanced lesions in the liver in a short time, even though only moderate amounts of carcinogen were used in this experimental series. These investigations demonstrate clearly the participation of pituitary factors in the genesis of liver tumours. Considering the similarity in response of males and females, it would appear that the pressure of the hormonal stimulation is so strong as to overcome sex-linked differences.

By means of this system and carcinogenic hydrocarbons, Furth *et al.*[11] observed mammary cancer development in female rats (see ref. 15). In contrast, there was no sign of mammary cancer in our experimental series. The mammary glands in both male and female rats were filled with milk cysts and were obviously functional. Possibly, the animals have not survived long enough or insufficient carcinogen was present at the level of the mammary gland to inhibit normal functioning of the gland. Some years ago, Cantarow, Paschkis *et al.*[16] proposed the idea that carcinogenesis proceeds best in a hyperplastic but non-functional gland, but does not occur in a hyperplastic and functioning organ.

The results obtained warrant an extension to a study of the applicability of the joint action of hormones and chemicals to liver carcinogens of different potency. In view of the higher sensitivity of this system, it is conceivable that compounds with weak carcinogenic activity can be detected more readily by this means. In any event, the rapidity with which the tumours arise might make this system suitable as a screening technique for carcinogenicity. Furthermore, the pituitary tumour used in the present instance generated a number of hormonal factors[12,17]. It will be of interest to determine whether individual hormones produced by this or other transplantable pituitary tumours as well as additional implants of the pituitary gland itself can accelerate liver carcinogenesis. The present investigations are suggestive in respect to a promoting effect of pituitary factors in liver carcinogenesis. Dissection of the individual sequences involved may throw some light on the possible operation of a sequential multi-stage effect in liver carcinogenesis, as it is recognized with respect to skin carcinogenesis[18].

We thank Dr. J. J. Furth and Dr. R. W. Bates for advice and also for supplies of the *MtT/F4* tumour, and Drs. P. Kotin, H. Stewart, T. Dunn and K. Snell for histopathological counsel.

Carcinogenicity of Preheated Fats

Roffo[1] claimed to induce gastric adenocarcinoma in rats after feeding fats preheated to 350° C for 30 min. However, several authors[2–4] repeating Roffo's experiments have failed to find glandular tumours in the stomach. Later, British investigators have examined the possible carcinogenic action of preheated cottonseed oil *per os* in mice and hamsters, but again without success[5]. In view of the repeated failure of the experiments when giving the fat orally, we attempted to induce glandular neoplasms by injecting fat—preheated to 360°–365° C for 30 min—into the stomach wall of the guinea pig, a rodent with a purely glandular stomach. The series reported here is an extension of a preliminary observation reported previously[6].

Sixty-five female guinea pigs with an average initial body-weight of 470 g were used. The fat to be injected was obtained from the peritoneal cavity—perirenal and mesenteric fat—of guinea pigs. The adipose tissue was minced with scissors in a Petri dish, placed in an open Erlenmayer flask, heated to 360°–365° C for 30 min, filtered (filter paper) to eliminate carbonaceous residue and cooled. The fat used in control animals—receiving non-heated fat—was extracted by ether. Both kinds of fats were warmed to a liquid state (22°–25° C) for injection. Each animal received an injection of 0·05 c.c. of preheated fat into the ventral wall of the fundus and the same amount into the wall of the antrum, except the animals killed at 150 days' post-injection, which received a single dose of 0·10 c.c. into the wall of the antrum only. Usually the fat was

Table 1. Effects of Intramural Injection of 0·05 c.c. of Preheated Fat on the Fundus and on the Antrum of the Guinea Pig

Group	Treatment	No. of animals	Days after injection	No. of animals bearing gastric lesions	Gastric lesions (per cent)	Gastric lesions*
I	Non-heated fat	9	17–18	0	0	—
II	Non-heated fat	7	90	0	0	—
III†	Non-heated fat	6	150	0	0	—

VII†	Preheated fat	6	150	6	100·0	Focal hyperplasia of mucosa (4); glands infiltrating submucosa (3); infiltration of muscularis propria (1); diverticulum (3)
VIII	Preheated fat	10	240	4	40·0	Focal hyperplasia of mucosa (2); glands infiltrating submucosa (2); diverticulum (1)

* Numbers in parentheses indicate number of lesions.

† In this group, a single dose of 0·10 c.c. in the wall of the antrum was injected.

deposited into the submucosa or the muscularis propria. Twenty-nine animals were injected with non-heated fat and 36 with preheated fat. One animal which received non-heated fat and died from an infectious disease at 60 days' post-injection (showing no gastric lesion) was not included in Table 1. For the schedule of death see Table 1.

The gastric lesions, observed microscopically, are summarized in Table 1. In the present series only local effects in the stomach were observed. None of the 28 control animals showed gastric lesions. On the contrary, in 18 out of 36 animals receiving preheated fat gastric lesions were found. These consisted mainly of focal hyperplasia of mucosal epithelium, diverticula, and glandular infiltration of submucosa through perforation of muscularis mucosæ sometimes at two separate points. In some cases these lesions were found in association with one another. In one case the lesion consisted of infiltration of muscularis propria by epithelial foci exhibiting hyperchromatic anaplastic cells. In addition, control and experimental animals showed various inflammatory and degenerative changes at the site of injection. The difference in incidence of lesions between control and experimental groups is highly significant ($P < 0{\cdot}001$). With respect to the carcinogenicity of non-heated fat, there was not an adequate number of control animals to prove conclusively that it has no carcinogenic activity. Furthermore, because non-heated fat was extracted by ether, in order to avoid heating, it is possible that ether extraction eliminated some ether-insoluble substance with a weak carcinogenicity. The diverticula and infiltrating lesions induced in the present series show striking morphological and histogenetic similarities to the precancerous lesions induced by 3-methylcholanthrene deposited on the gastric serosa[7], implanted[8], or injected[9] into the stomach wall of guinea pigs. We have observed under all these conditions infiltrating lesions originating from basal glands, sometimes perforating the muscularis mucosæ at multiple points in association with diverticula. Furthermore, the case of invasion of muscularis propria suggests the possibility that, when permitting preheated fat to be in contact with glandular cells for longer periods of time, a malignant change may occur. However, we have not classified the present epithelial lesions as precancerous because we have not at this time information on their progression.

Finally, it is necessary to emphasize that a great part of the disagreement among experimental results on the carcinogenicity of naturally occurring lipoid substances is due mainly to the different: (*a*) chemical composition of the material tested, and, furthermore, the variable composition of similar commercial samples, for example, lards and oils; (*b*) temperatures reached during heating; (*c*) duration of the heating process; (*d*) species and strains of rodents used, and (*e*) duration of the experiments (for references see Zaldívar[10] and Arffmann[11]).

I thank Prof. G. W. Casarett for diagnosis of some microscope slides and helpful criticism on this work.

RADIOBIOLOGY

Induction of Mutations and Killing of Cells in Irradiated Spermatogonia of *Drosophila*

In experiments where *Drosophila melanogaster* spermatogonia were irradiated in the 20-h old embryo with doses of 0 r., 55 r., 110 r., 160 r. and 310 r. given at 25 r./min, and the induction of sex-linked recessive lethals observed, a non-linear dose effect curve was found[1]. This curve had a rather flat maximum for doses of 110 r. and 160 r. (about 0·15 per cent lethals above controls), whereas 310 r. gave no increase in lethal frequency above the control value. These results were based on slightly more than 100,000 *X*-chromosomes tested (Fig. 1).

It was presumed that differential killing of cells which carried mutations was the mechanism involved. In an attempt to explain the results quantitatively, a mathematical model for the irradiated population of spermatogonia was formulated. This model is based on the assumptions that: (*a*) there is a cyclic variation in cell radiosensitivity as regards induction of mutations as well as regards cell killing[2,3]; (*b*) only damage inflicted in the sensitive phase need be considered in relation to the above results. If *Drosophila* spermatogonia are assumed to have a radiogenetic sensitivity of $2{\cdot}0 \times 10^{-5}$ sex-linked lethal mutations per r. (about the same as sperm), and in the sensitive phase a survival curve with $LD_{50} = 135$ r. and extrapolation number = 3·0, and that 0·1 of the spermatogonial population is in the sensitive phase at the time of treatment, the theoretical dose effect curve for recovered mutations which can be calculated from the

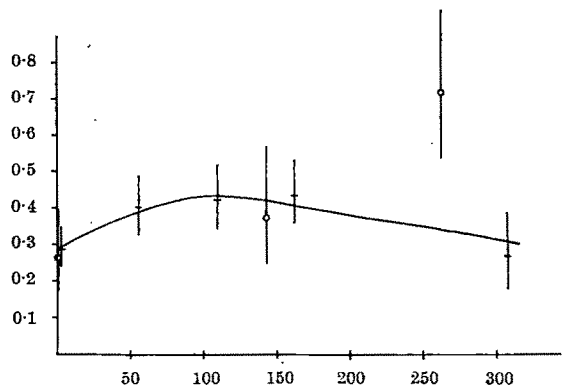

Fig. 1. Frequencies of sex-linked recessive lethals (per cent) after treatment of spermatogonia with doses given at 25 r./min (+) or protracted over 8 h (○). Full line shows theoretical curve for scorable lethals based on hypothetical values for cell sensitivity and cell survival. Vertical lines indicate 95 per cent expectation interval (ref.10)

model fits the experimental results in a rather satisfactory way[4] (Fig. 1).

On the further assumptions that sub-lethal radiation damage is repaired completely from one cell generation to the next[5], whereas 'genetic' damage is not, the hypothesis led to the conclusion that if a given dose were protracted over several cell generations, the observable genetic damage should be higher than that found after acute treatments. This conclusion has now been tested with doses of 144 r. and 267 r.

The same experimental procedure was used as before. Spermatogonia were irradiated in wild-type embryos/young larvæ. The irradiated ♂♂ were afterwards mated singly to Basq ♀♀. Only one heterozygous ♀ among the offspring of each such mating was then tested for the presence of a lethal-bearing *X*-chromosome, whereby the problems connected with clusters of mutations were avoided. Irradiations were performed by means of a 5-c. ^{137}Cs-unit. Doses were given over 8 h, $16 \pm 0{\cdot}5$ to $24 \pm 0{\cdot}5$ h after egg laying. 144 r. and 267 r. were given simultaneously to different batches of eggs collected from the same group of layer ♀♀. Eight irradiations were performed during the autumn of 1962. The totals are given in Table 1 and Fig. 1. The results seem to support the hypothesis of differential killing as an explanation for the results after acute irradiation of spermatogonia. The quantitative conformity with the hypothetical value for the radiogenetic sensitivity is also fairly good for a first attempt: $1{\cdot}7 \times 10^{-5}$ mutations per r. after 267 r., as compared with the hypothetical $2{\cdot}0 \times 10^{-5}$ mutations per r.

Table 1. Frequencies of Sex-linked Recessive Lethals after Protracted Treatments of Spermatogonia. Upper and Lower 95 per cent Expectation Limits calculated according to Fisher and Yates (ref. 10)

	0 r.	144 r./8	267 r./8
Chromosomes tested	6,934	4,835	5,788
Lethals found	18	18	41
Lethal frequency (%)	0·26 (0·39 / 0·17)	0·37 (0·56 / 0·25)	0·71 (0·94 / 0·53)

The results show that protracted irradiations under some conditions may have a higher observable genetic effect than have acute treatments. This is a dose rate effect in the opposite direction of that found by Russell *et al.*[6] in the mouse and Oster *et al.*[7] in *Drosophila* ♀♀ and sought by several authors in other materials[8]. The present effect is similar to that found by Tazima *et al.* after irradiation of silkworm larvæ 3–10 days old, and opposite that found after treatment of earlier stages[9]. It is believed that consideration of the dynamics of the irradiated cell populations in the different systems may provide clues to an understanding of the divergent findings.

BIOLOGY

Accumulation of Amino-acids in Plant Cell Tissue Cultures

It was recently reported that when plant cell tissue cultures derived from sycamore cambial callus (*Acer pseudoplantanus L*) were grown with limited access to air, there was a marked reduction in the amount of leucoanthocyanins produced although there was little effect on aldohexose concentration[1]. It has now been found that, in limited air, cell cultures from callus of sycamore, bean (*Phaseolus vulgaris, L*), rose (*Rosa* sp., var. Dr. van Fleet), and *Haplopapus gracilis* grown on agar slopes as before[1], all show a marked increase in the amount of free amino-acids compared with tissue grown with free access to air. Again little or no change was found in the concentration of sugars (Table 1), nor, in the case of the sycamore callus, in the total perchloracetic acid-soluble ribonucleic acid. Analyses of the changes with time in the relative proportions of carbon dioxide and oxygen, using a Fisher gas analyser, in the culture bottles showed that, as expected, there was a build-up of carbon dioxide to ~20 per cent and a decrease of oxygen to ~0·5 per cent in the sealed bottles.

Table 1. Amino-acids and Aldohexoses in Cultures grown (*a*) with and (*b*) without Free Access of Air

Culture	Amino-acids (*a*)	Amino-acids (*b*)	Sugars (*a*)	Sugars (*b*)
Bean	8·5	40·2	67	60
Sycamore	4·2	25·1	109	103
Rose	19·4	47·0	7·3	5·8
Haplopapus	7·2	60	10·3	10·8

All values expressed as μmoles/g callus in terms of β-phenylalanine and glucose respectively.

To determine whether the observed increase in total amino-acid concentration was due either to increased carbon dioxide or decreased oxygen, callus tissue was grown in bottles kept in vacuum desiccators filled with artificial gas mixtures containing different proportions of carbon dioxide and oxygen (Table 2). The desiccators were evacuated and filled with the appropriate gas mixtures every other day. The results indicate that both increased carbon dioxide and decreased oxygen lead to an accumulation of amino-acids. The effect of growth in restricted air increasing the concentration of amino-acids

Table 2. Total Amino-acids in Cultures grown in Gas Mixtures containing Different Proportions of Carbon Dioxide and Oxygen

Gas mixture: Carbon dioxide (%)	Gas mixture: Oxygen (%)	Total amino-acids: Bean	Total amino-acids: Sycamore
0	20	6·5	2·5
10	20	22·9	—
20	20	19·5	—
5	15	6·5	2·5
10	10	13·8	4·7
15	5	24·6	9·5
20	1	28·2	14·2
0	1	27·7	—

Values for total amino-acids expressed as μmoles/g callus in terms of β-phenylalanine.

also occurred when 0·1 per cent yeast extract was added to the growth medium, but not when a rich source of amino-acids (1 per cent acid-hydrolysed casein) was used. This would indicate that the growth factors present in yeast extract have no effect on the accumulation process.

Paper chromatographic analyses of the accumulated amino-acids showed that there were marked quantitative differences in the relative proportions of each, the most striking being a large increase in γ-aminobutyric acid, an effect which was accentuated when the tissue was grown in the presence of yeast extract. Other workers[2] have reported a similar accumulation of γ-aminobutyric in other organisms. The relationship between this amino-acid and related metabolites in cell tissue culture is now being examined.

We thank Dr. N. Sutherland for supplying the isolates of *Haplopapus gracilis* and *Rosa* var. Dr. van Fleet, and Dr. D. H. Northcote for the isolate of *Acer pseudoplantanus L.* One of us (R. L. W.) thanks the Director, Tea Research Institute of Ceylon, for permission to publish this communication.

Intermittent Germination of *Capsella*

Previously, I have directed attention to the prevalence of intermittent germination as a feature of the most successful of our annual garden weeds and suggested that human cultivation activities have probably effected an artificial selection of strains that has accentuated this feature[1]. Attention was there directed to the need for sowing freshly ripened seeds from individual plants to avoid the concealment of this feature, through overlap of the germination flushes from seeds of different individuals or seeds stored for varying periods. These conditions, however, frequently impose a severe limitation on the number of seeds available for any one test and it might therefore be suggested that if a considerably augmented number of seeds were simultaneously ripened the intermittence would be appreciably diminished or might actually disappear.

Last summer I was fortunate in finding an exceptionally large plant of the *Capsella simplex* type from which, on July 16, I was able to obtain no less than 2,327 ripe seeds which were sown immediately on a pan of soil maintained thenceforth in a moist state, in an unheated glasshouse so as to avoid possible interference by birds. The conditions were thus similar to those in Nature except that the maximum daytime temperatures were higher than those in the open. As germinations occurred the seedlings were removed daily with forceps and their numbers recorded, when also their distribution was observed, and it may be stated at the outset that the individual seedlings of the different flushes appeared to be more or less evenly dispersed and no 'edge effects' were manifest.

The results, together with the maximum and minimum temperatures, are presented in the accompanying graph (Fig. 1). It will be seen that the great majority of the germination flushes occurred, as might have been anticipated, when there was a rise of temperature, but it must be emphasized that such temperature changes may occur without any corresponding germination flush, as can be seen, for example, about September 12, November 22 and February 15. It is very obvious, from a comparison of the germination fluctuations with the temperature changes, that the increasing warmth triggers off the germination of those seeds, and only those, that are in a state for such stimulation.

Two major aggregations of daily germinations are seen to have obtained, namely in the autumn and spring respectively, but even at the periods when there was no actual interruption of the daily germinations there is a marked irregularity in their numbers which, from its multimodal character, probably represents concealed intermittence.

Despite the large number of seeds involved, of which more than 77 per cent proved viable, the intermittent

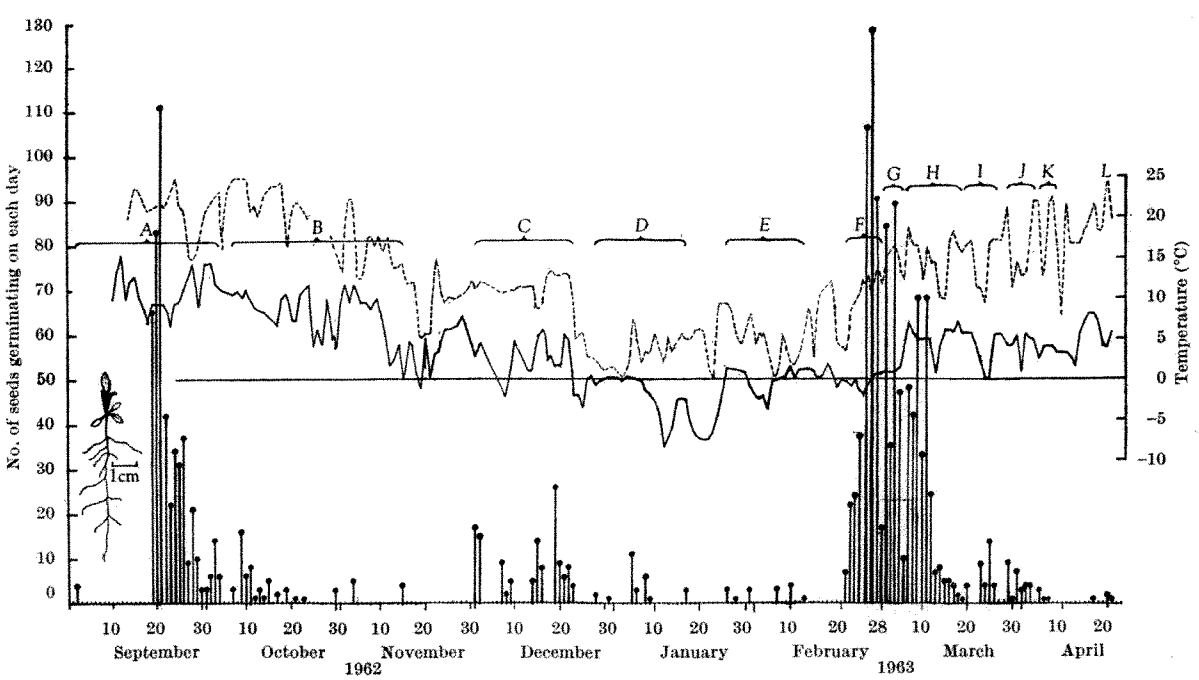

Fig. 1. Daily germinations from 2,327 ripe seeds obtained from a plant of the *Capsella simplex* type sown on July 16, 1962. Period *A*, 501 seeds obtained in 33 days (21·5 per cent); *B*, 62 from 36th to 74th day (2·6 per cent); *C*, 129 from 90th to 112th day (5·5 per cent) *D*, 27 from 117th to 137th day (1·1 per cent); *E*, 15 from 146th to 163rd day (0·6 per cent); *F*, 432 (18·6 per cent); *G*, 265 (11·4 per cent); *H*, 307 (13·1 per cent); *I*, 35 (1·5 per cent); *J*, 28 (1·2 per cent); *K*, 5 (0·2 per cent); *L*, 4 (0·17 per cent). This represents a total of 1,810 seeds during period of 230 days (77·7 per cent). – – –, Maximum day temperatures; ——, minimum night temperatures

character of the germinations is quite conspicuous. From the first germinations on September 2 to the last in the following April, they are spread over a period of no less than 215 days. If we ignore the fluctuating numbers and only regard periods when there were uninterrupted daily germinations, these number no less than thirty, forming about ten groups of active germination. Germinations occurred on 96 of the 215 days over which they were spread. It should, however, be stressed that biologically a succession of flushes of germinations probably have a similar biological significance whether interrupted or not unless the actual discontinuity be so marked, as in periodic types of germination, as to preclude the build-up of pests or predators.

Incidentally, it may be noted that during the very severe weather of January the seedlings were as brittle as glass, but some that had been transplanted when removed showed no sign of injury after they had thawed.

We could reasonably expect that the factor, or more probably factors, responsible for the differing natural dormancy of contemporaneous seeds would exhibit degrees of intensity from being very marked to perhaps only slight and that this variation would be normal and continuous. The discontinuity that we actually observe might be imparted by the erratic occurrence of the meteorological conditions that bring about the marked temperature changes which observations have shown stimulate germination of these seeds that have attained a condition to respond. For *Capsella*, such an interpretation conforms to the observed facts that while all the germination flushes occur in relation to abrupt changes of temperature such changes may nevertheless occur without any accompanying germination response, presumably because no seeds were contemporaneously in an appropriate physiological state.

Electron Paramagnetic Resonance in Non-irradiated Bone

The generation of electrical potentials by bone subjected to mechanical stress has been recently reported by two groups of investigators[1,2]. Bassett and Becker suggested a semiconduction mechanism as being the source of the phenomenon, while Shamos *et al.* favoured a classical piezo-electric mechanism similar to that earlier described by Fukada and Yasuda[3]. The semiconduction theory has recently been reported on in more detail[4] and evidence presented for the formation of multiple *pn* junctions from the apatite crystal (*p* type) collagen fibre (*n* type) in the bone matrix. Similar inorganic *pn* junctions have been shown to be exceedingly stress sensitive[5,6].

Since the semiconduction theory would require the presence of free charge carriers while the piezo-electric theory would have no such requirement, the application of electron paramagnetic resonance techniques to this problem seemed to be of interest. If semiconducting materials with adequate concentration of donors are present in bone, resonance signals should be observable without previous irradiation, and should be increased by light and thermal activation and possibly by mechanical stress. Electron paramagnetic resonance signals have previously been reported in electron irradiated bone[7] and in X-ray irradiated teeth[8] and bone[9]; no signals have been reported in non-irradiated material.

Cortical bone samples, human tibia and bull-frog tibia, were obtained by surgical dissection from extremities rendered bloodless by tourniquet or vessel ligation. The periosteum and inner cancellous bone were removed and

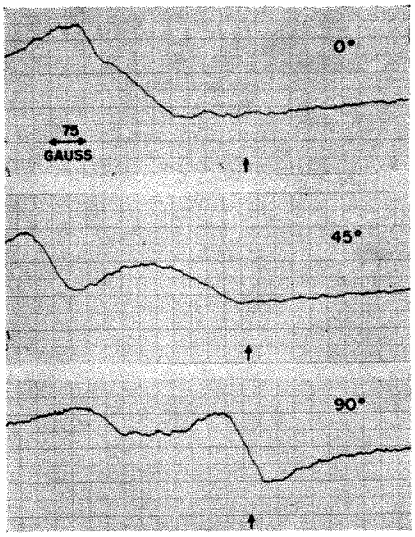

Fig. 1. Electron paramagnetic resonance spectra obtained from amphibian whole cortical bone. The orientation of the sample long axis relative to the *H* field is indicated in the upper right on each tracing. The arrow indicates *g* 2·0 value

cortical fragments approximating 3 mm × 3 mm × 5 mm were obtained by osteotome. Further dissection was done with quartz knife and probe under 20 times magnification. All surfaces were shaved free of any possible metallic contamination and sections with visible vascular capillaries were discarded. Final specimens were approximately 0·5 mm wide and 3 mm long, the original long axis being represented by the larger dimension. Only dense mature cortical bone was utilized. Samples were mounted on quartz filaments with a small amount of 'Cenco' red wax and suspended in 5-mm diameter quartz tubes, in such a manner that the angular relationship between the long axis of the bone sample and the main magnetic field (*H*) could be altered. Control tracings were made in each case by removing the sample, retaining the original mounting wax, quartz filament and tube. All electron paramagnetic resonance spectra were obtained at room temperature, the first derivative curve being recorded. A Varian *X* band spectrometer with 100-kc/s field modulation was used in conjunction with a 6-in diameter Varian electromagnet with ring shim pole caps and gap diameter of 2·58 in.

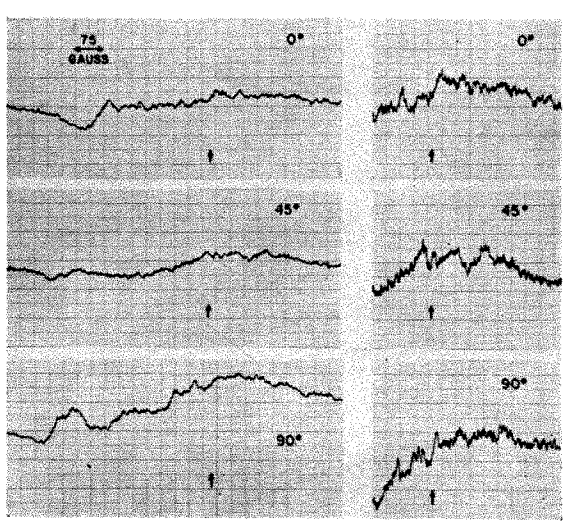

Fig. 2. Electron paramagnetic resonance spectra obtained from human whole cortical bone. Sample long axis orientation and *g* 2·0 value are indicated in the same fashion as in Fig. 1. The tracings at the left were obtained with similar amplification to those of Fig. 1. The recordings to the right were obtained with an amplification of three

Resonance signals with g values dependent on the angular relationship of sample long axis to H field were observed in all samples of bone from each species. In amphibian bone (Fig. 1) a large well-defined resonance about 200 gauss wide was noted in the vicinity of g 2·3, with a shift in g value with change in angular orientation. In the 90° position a well-defined, almost symmetrical resonance appeared at g 2·0 which was much more anisotropic, appearing to merge with the g 2·3 peak in the 0° position. In human bone (Fig. 2) a similar well-defined resonance was found in the g 2·3 vicinity, being more prominent in the 0° and 90° orientation than in the 45° with again moderate g value anisotropy. A very broad resonance signal appears, most prominently at 90° orientation, reaching a peak at approximately g 1·8. Higher amplification scans of the g 2·0 area demonstrated a small superimposed resonance, about 35 gauss wide with a g value of 2·0 in the 90° position. This signal is light sensitive, increasing in amplitude with irradiation from a wide band (2000–10000 Å) source.

The similarity of the two major resonances obtained from non-irradiated bones of two different vertebrates as well as the evident anisotropic characteristics of the signal indicate that they are produced by actual components of the bone rather than surface contamination. At this time neither resonance can be definitely ascribed to a free charge carrier population such as is present in doped semiconductors[10]. Identification of the substances involved requires further separation and purification procedures.

A Graphical Method for comparing the Ratio of the Number of Cells to the Volume of Medium in Tissue Culture Containers of Various Sizes

IN the course of virus yield studies it is often necessary to convert a tissue culture system from one size container to another in such a way that the ratio of the number of cells to the volume of medium remains constant. An easy way of determining the various medium volumes which will give this constant ratio is to plot the relevant data graphically.

From previous work carried out in this Department, a value for the number of cells of a given tissue culture per unit area of confluent cell sheet was available. This value was obtained from six hundred counts of cells grown on cover-glasses. The confluent cell sheets were stained and a total of forty areas were counted on each cover-glass using stage and ocular micrometers, ten cover-glasses being counted for each batch of cells. The experiment was repeated six times using a different batch of cells each time. The particular tissue cultures used in this experiment were primary monolayers of embryonic chick fibroblasts and the mean value obtained was 1,150 cells/mm² of cell sheet.

Knowing this value, it was then necessary to measure the total area of the cell sheet in each type of flat bottle under consideration. As the contours of the bottles made

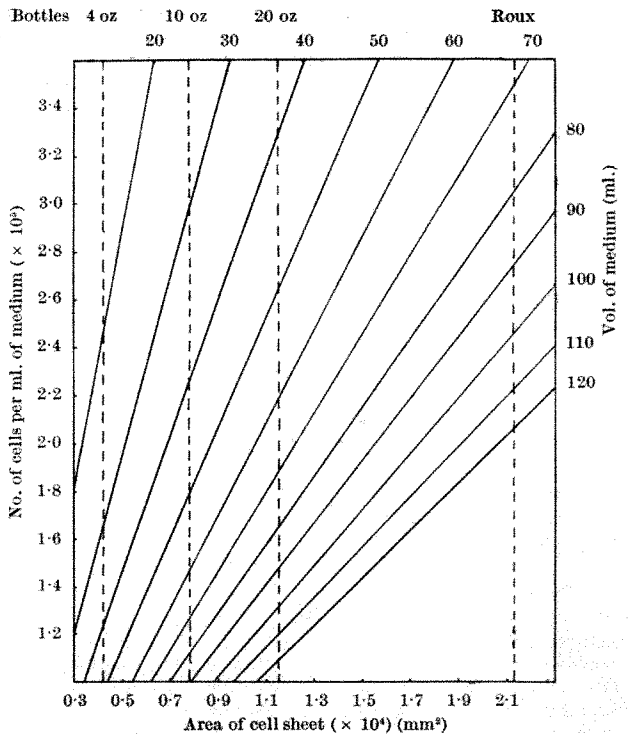

Fig. 1. No. of cells/ml. of medium plotted against area of cell sheet calculated for chick embryonic fibroblasts of density 1,150 cells/mm²

the exact shape of the cell sheets irregular it was found that the best way to measure the area was first to mark the edge of the cell sheet on the outside of the bottle. This outline was then traced on to thin paper and from there copied on to millimetre squared paper. A count of the squares enclosed by this outline gave the area of the cell sheet in square millimetres directly. Twelve experiments were made in this way to obtain a mean value.

The ratio of number of cells to volume of medium (expressed as cells/ml.) can be calculated from the following equation:

$$R = \frac{AN}{V}$$

where R = cells/ml.; A = area of cell sheet (mm²); N = cells/mm² = 1,150 (as determined); V = volume of medium (ml.).

Hence if R is plotted against A (for different sizes of bottles) then a straight line will be obtained with a slope of N/V. As N is a constant for a given tissue, then the slope will be inversely proportional to V and as the volume increases so the slope of the line decreases. Therefore, if graphs of R against A are plotted for various values of V then a series of straight lines with different slopes will be obtained.

Fig. 1 gives the values for the cell sheet areas corresponding to four sizes of bottle (4 oz., 10 oz. and 20 oz. medical flats and Roux) which are marked by the dotted lines. The point where the dotted line intersects a continuous line marks the value of R at that volume of medium represented by the continuous line.

This method can be used to translate a system from one type of bottle into the equivalent for another type. A 20-oz. bottle is represented by the dotted line on the graph at $1{\cdot}15 \times 10^4$ mm² on the A axis. If this bottle contains 60 ml. of medium then the equivalent in other sizes of bottle is found by placing a ruler across this line parallel to the A axis and where it intersects the 60 ml. line. Where the ruler crosses the 10 oz. line the nearest volume line is for 40 ml. (A line for 41 ml. would be more accurate if drawn.) Similarly for a Roux bottle the nearest volume line is 110 ml.

It can be concluded that a 10-oz. bottle with 40 ml., a 20-oz. bottle with 60 ml. and a Roux bottle with 110 ml. of medium all have approximately the same cell to volume of medium ratio. Hence different cell systems can be rapidly converted from one size of bottle to another while still maintaining the relationship between the number of cells and the volume of medium.

Effect of Electrostatic Fields on Cell Mitosis

From quantum mechanical calculations on the electronic structure of DNA[1–3] a mechanism was proposed for the onset of DNA-duplication[3,4]. It has been assumed that the mobile π-electrons of the macromolecule, which, according to Eley and Spivey[5], cause the semi-conductivity of DNA, can be polarized by the effect of local electrostatic fields present inside the cell. As a result of polarization free electron charges may appear at the end of the DNA double-helix; the repulsion between the charged nucleotide bases at the ends of the molecules may lead to the breaking of the bonds between them and thus induce the unwinding of the double-helix[3,5]. The unwinding of the helix being, according to the Watson–Crick duplication mechanism[6], the starting point of DNA duplication, it seemed reasonable to suppose that the appearance of free charges at the ends of the molecule might induce DNA multiplication. It was therefore decided to examine the behaviour of cell cultures exposed to the effect of strong electrostatic fields[4].

In the present experiments chick-embryo heart fibroblast cultures, cultivated in plasma coagulum with 20 per cent chick-embryo extract and prepared using the hanging-drop method[7], have been exposed to the effect of an electrostatic field. The latter was produced by a d.c. voltage source (designed and constructed by the Central Research Institute for Physics, Budapest) to supply a potential difference of 14–25 kV. A voltage of 15 kV was led into the parallel plates of a capacitor with reinforced insulation. The plates were 30 cm × 14 cm in size and 1 cm thick; the distance between them was 1 cm during the experiments. (The actual field strength in the cells is until now unknown in our experiments.)

The cultures contained in depression slides 0·4–0·5 cm thick were placed between the two plates of the capacitor and kept there for 8 and 4 h respectively. In the 8-h series the cultures were exposed to the electrostatic field 18–20; in the 4-h exposures, 1 h after explantation. Control specimens, their number corresponding to the cultures under investigation, were kept in the same laboratory at identical temperatures and for identical lengths of time. After exposure to the electrostatic field, the cultures along with the controls were placed for 18 h into a thermostat kept at 37° C. Thereafter, the material was fixed in Carnoy-fluid and stained by Giemsa's method.

The mitotic indices of the cultures which underwent treatment and those of the control specimens as well were determined by direct counting. Table 1 shows the results of both experimental series.

Table 1. Mitotic Indices of the Cultures exposed to the Effect of an Electrostatic Field, and of the Control Cultures

	8 h						4 h			
Series	1	2	3	4	5	6	1	2	3	4
N	12	14	4	20	6	12	20	12	16	16
$\overline{X}$	2·50	2·70	2·00	2·00	5·70	7·24	2·79	3·81	1·68	2·53
$\overline{X}_c$	1·00	1·70	1·30	0·90	3·80	5·62	2·73	2·62	1·61	2·36
S_x	0·19	0·25	0·06	0·11	0·60	1·51	0·32	0·59	0·37	0·41
S_c	0·16	0·13	0·14	0·10	0·19	1·15	0·29	0·24	0·28	0·44
SD	5·95	3·56	4·58	7·36	3·01	0·85	0·14	1·87	0·15	0·69

Here N is the number of the cultures, $\overline{X}$ and $\overline{X}_c$ respectively correspond to the algebraic mean value of the mitotic indices of the exposed, control cultures, S_x and S_c are the standard deviation of the respective mitotic indices, and finally:

$$SD = \frac{\overline{X} - \overline{X}_c}{\sqrt{S_x^2 + S_c^2}}$$

is the index of significance. According to the usual biological practice, experiments where $SD > 2{\cdot}00$ is obtained are considered as having a significant difference[8].

It appears from Table 1 that the cultures exposed to the electrostatic field have in each case a larger mitotic number than the control specimens. 8-h exposures gave significant differences between the mitotic indices for all cultures but one. (The SD values vary from 3 to 7·4.) In the 4-h treatments, on the other hand, these differences were found to be insignificant (SD values varying from 0·1 to 1·9).

This preliminary investigation does not, of course, provide definite evidence for our hypothesis regarding multiplication of DNA. It may, however, be stated that the results obtained are at least not in contradiction with it.

Incidence, Size and Shape of Meta-cortex Fibres in Wool

The presence of a basophilic, sulphur-deficient core in some wools has been reported[1,2], and the core has been called the meta-cortex to differentiate it from the ortho- and para-portions of the cortex. Recently, solvent-cleaned samples of several types of wool have been stained by being boiled for 15 min in methylene blue (0·05 g/l.) at pH 6·5, thoroughly rinsed, and afterwards cross-sectioned using a Hardy microtome. The fibre cross-sections were examined for the presence of a medulla, or of a stained meta-cortex, and their major and minor axes were measured using a projection microscope at a magnification of 500. For each sample approximately 500 fibres were examined. The percentages in each class are set out in Table 1.

Naturally, the samples cannot be taken by themselves as characteristic of the whole breed or type—in an

Table 1. Percentage of Medullated and Cored Fibres

Type	Ortho/para only	Meta-cortex fibres	Medullated fibres
South Australian merino 60's	97	3	—
Montevideo 60's	100	—	—
Australian 58's	100	—	—
Southdown 60's	84	16	—
Shropshire	95	5	—
Corriedale	98	2	—
New Zealand 56's	92	8	—
Romney 48's	91	2	7
Romney lamb	94	1·5	4·5
Wensleydale	79	21	(may include some medullated)
Lincoln	89	11	,,
Swaledale	85	15	,,
Cheviot	40	32	28

earlier investigation a much higher proportion of another Corriedale sample contained meta-cortex. However, the differences between the merino types, the Downs, the English Longwools and the mountain types are fairly clearly marked.

The shapes of the cross-sections, as expressed by the ratios of major and minor axes, also show some distinctions, as will be seen from Table 2.

Table 2. Ratio of Major/Minor Axes

Type	Ortho/para only	Meta-cortex fibres	Medullated fibres
South Australian merino 60's	1·21	1·17	—
Montevideo 60's	1·24	—	—
Australian 58's	1·29	—	—
Southdown 60's	1·30	1·53	—
Shropshire	1·33	1·44	—
Corriedale	1·27	1·12	—
New Zealand 56's	1·25	1·28	—
Romney 48's	1·25	1·31	1·41
Romney lamb	1·24	1·29	1·44
Wensleydale	1·20	1·54	—
Lincoln	1·18	1·18	—
Swaledale	1·24	1·29	not measured
Cheviot	1·30	1·48	1·63

In most cases the fibres containing a meta-cortex were more elliptical than those without. The high axial ratio of the Down types is notable, some Southdown fibres being markedly concave on one side. The remarkably circular cross-sections of most Longwool fibres are, of course, well known.

The products of the mean semi-axes are shown in Table 3 for the various types.

Table 3. Products of Mean Semi-Axes (μ^2)

Type	Ortho/para only	Meta-cortex fibres	Medullated fibres
South Australian merino 60's	172	194	—
Montevideo 60's	154	—	—
Australian 58's	210	—	—
Southdown 60's	256	342	—
Shropshire	316	440	—
Corriedale	194	263	—
New Zealand 56's	199	282	—
Romney 48's	418	608	687
Romney lamb	303	528	613
Wensleydale	330	420	—
Lincoln	462	752	—
Swaledale	253	536	—
Cheviot	310	496	652

The average area of cross-section of the cored fibres is, in every type, greater than the average of the uncored, and both the major and minor semi-axes are likewise bigger for the cored fibres than for the others. However, there does not appear to be a maximum value of size, above which the fibre must be cored or medullated, since the areas of cross-section of the Romney and Lincoln ortho/para fibres are greater than those of the meta-cortex fibres in the samples of Southdown, Corriedale and New Zealand 56's. The size and number of the fibres with a meta-cortex suggest that they might represent an appreciable fraction of the fibres grown in primary follicles, and an investigation of this might be desirable.

CYTOLOGY

An Effect of Thyroxin on the Fine Structure of the Rat Liver Cell

We have recently observed a striking change in the fine structure of the liver cells of rats given large doses of thyroxin. Wistar rats (Alderley Park strain 1) were given thyroxin in their diet at levels of 0·001 or 0·005 per cent. Control animals were given unmedicated diet. After one, two or three weeks on the diet, groups of three test and three control animals were killed, small fragments of liver were fixed in buffered 1 per cent osmium tetroxide, and processed through 'Araldite'. Thin sections were cut and stained with lead citrate[1], and examined in the electron microscope.

The changes observed were fully developed in animals killed at one week and did not differ in animals killed later. They consist of a moderate increase in the numbers of

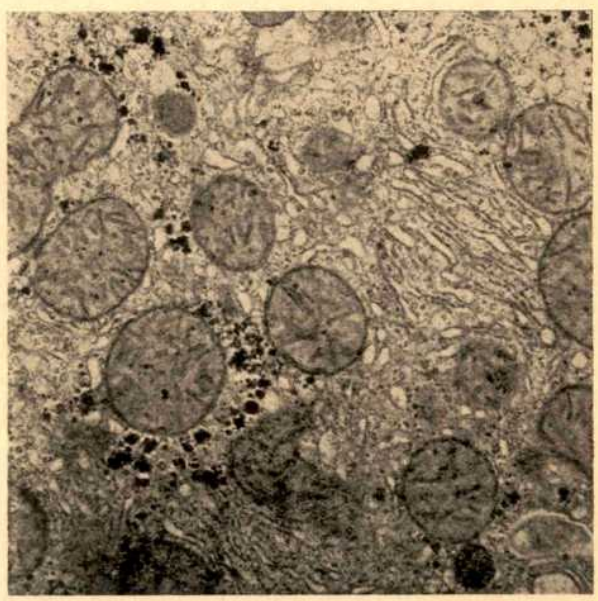

Fig. 1. Control rat. Group of mitochondria. (Lead citrate stain. × *c.* 9,000)

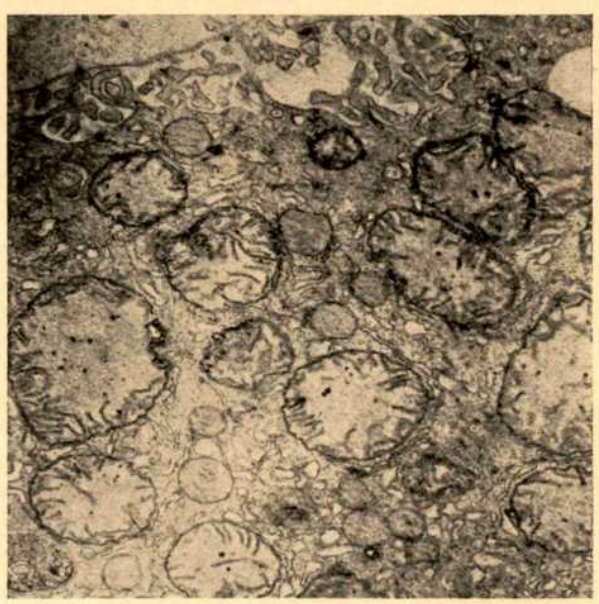

Fig. 2. Rat after 1 week thyroxin treatment. Group of mitochondria near sinusoidal margin. Note swelling and increase in number of cristæ mitochondriales. (Intra-mitochondrial granules are also more prominent than in the control.) (Lead citrate stain. × *c.* 9,000)

mitochondria, some swelling of these organelles, and a very marked increase in the number of cristæ mitochondriales found in each organelle (Figs. 1 and 2). In addition, a number of large mitochondria of bizarre shapes were observed.

Changes in the mitochondria of liver cells of animals given thyroxin have been observed by Schulz, Löw and Sjöstrand[2]. They noted swelling and vacuolation of the mitochondria only. However, since the mitochondria are the site of respiratory enzymes, and since thyroxin increases cell respiration, the observations reported here provide a morphological basis for the known biochemical action of the hormone.

MICROBIOLOGY

Specificity of the Solute Requirement by Marine Bacteria on Primary Isolation from Sea-water

The partial replacement of sodium chloride in a culture medium for a marine bacterium by sucrose or potassium chloride was recently described[1]. The non-specific solute requirement was shown to control the rate of growth and under the conditions of experimentation was not concerned with osmotic fragility. Some previous workers found relatively little replacement of sodium salts by other solutes and concluded that the organisms being studied had little or no osmotic requirement[2,3]. In contrast, the solute requirements of the marine luminescent bacterium *Photobacterium fischeri*, both for growth and metabolism, were found to be non-specific and were considered to be primarily osmotic[4,5]. The various findings suggested the existence of species variation with respect to this property among marine bacteria. As a direct approach to a better understanding of this situation, samples of sea-water were plated directly on to media having either sodium chloride, potassium chloride, or sucrose as the principal solute. The purpose was to determine the proportion of cells in a natural inoculum which would allow a partial replacement of sodium chloride in the growth medium.

The basal medium contained 0·2 per cent trypticase ('BBL'), 0·001 M magnesium chloride, 0·005 M potassium sulphate, 0·0005 per cent ferrous sulphate, 1 per cent Oxoid 'Ionagar No. 2'. The medium was adjusted to *p*H 7 with a few drops of 2 M *tris* (hydroxymethyl) amino methane. Those media containing sucrose were supplemented with 0·2 per cent ammonium succinate to buffer the acidity possibly produced by some organisms. The solutes added are indicated in Table 1. Potassium chloride and sucrose were tested both in the presence and absence of a sub-optimal amount of sodium chloride to evaluate how frequently sodium ion could be demonstrated to be essential in a specific way to the growth of marine bacterial species. Three samples were taken from the Atlantic Ocean at Matanzas, Florida; for a comparison, one sample was taken from a small fresh-water pond. The plates were inoculated in triplicate with 0·1-ml. amounts; the inoculum was spread over the surface of the agar with a sterile bent glass rod. A one-hundred fold dilution of the pond water was used to give a comparable number of colonies. The cultures were incubated at 32° C and were observed at daily intervals through 72 h.

Table 1. Effect of Solutes on Colony Numbers obtained with Marine and Freshwater Samples

Addition to basal medium	Marine samples			Pond water
	A	*B*	*C*	
NaCl, 0·35 M	62	73	138	1
NaCl, 0·025 M	8	7	14	91
KCl, 0·35 M	5	9	25	2
KCl, 0·325 M; NaCl, 0·025 M	23	33	76	2
Sucrose, 0·5 M	15	14	35	5
Sucrose, 0·5 M; NaCl, 0·025 M	28	41	67	1
No addition	6	2	8	82

The values are the average number of colonies per plate; 0·1-ml. amounts of the marine samples were plated in triplicate; 0·1-ml. amounts of a 100-fold dilution of the pond water were plated in duplicate. The basal medium was 0·2 per cent trypticase, 0·001 M $MgCl_2$, 0·005 M K_2SO_4 and 0·0003 per cent $FeSO_4 \cdot 7H_2O$. The media were solidified with 1·0 per cent Oxoid 'Ionagar No. 2'.

The highest colony counts obtained from the marine samples occurred on the medium containing 0·35 M sodium chloride; this contrasted with the counts from the fresh-water sample where the highest counts were obtained on the media containing the lowest amounts of salt (Table 1). The minimal level of sodium chloride required by the majority of the marine bacteria was greater than 0·025 M, which was ineffective by itself; however, approximately half the maximal number of colonies grew in media containing, in addition to 0·025 M sodium chloride, either 0·32 M potassium chloride or 0·5 M sucrose. The latter solutes were much less effective in the absence of sodium chloride, indicating that for the majority of the organisms in the samples the sodium chloride could not be completely replaced. As compared with the basal medium, a larger number of colonies grew in that to which only sucrose was added; because of the presence of a complex nutrient like trypticase, this observation cannot be considered as evidence of growth in the absence of sodium. Replicate plates made using the original plates as templates indicated that most of the organisms which responded to partial replacement of sodium ions by potassium chloride responded in a similar way to sucrose; a few exceptions were observed which would accept only one or the other but not both.

The results support the view that variability occurs among marine bacteria with respect to the relative specificity of the requirement for sodium chloride and that approximately half the organisms studied would grow in media in which a substantial replacement of sodium chloride by sucrose or potassium chloride had been made.

This work was supported, in part, by the National Science Foundation grant 7075.

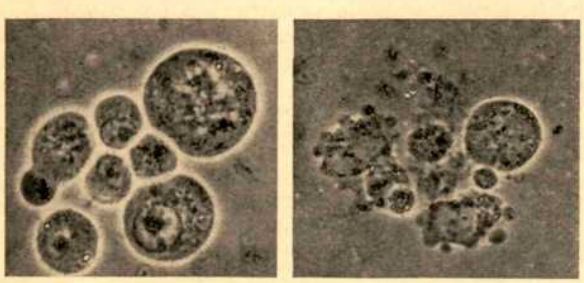
Effect of *Mycobacterium tuberculosis H37Rv* grown *in vivo* (*LH37Rv*) on Ehrlich Carcinoma Ascites Cells

Previous reports from this laboratory have shown that cells of *Mycobacterium tuberculosis H37Rv* separated from lungs of mice infected with this strain are coated with nicotinamide adenine nucleosidase (NADase) of the host[1]. Discussing the possible role of NADase adsorbed by the tubercle bacilli in the pathogenesis of tuberculosis, we have assumed that, on phagocytosis of tubercle bacilli, the nicotinamide adenine dinucleotide splitting enzyme may impair the electron transport system of the phagocyte, thus bringing about the death of the latter[2]. It should be recalled that a similar hypothesis was propounded by Bernheimer *et al.*[3], who found a remarkable correlation between the capacity of streptococci to produce extracellular NADase and leukotoxicity. The authors suggested that the leukotoxicity might well be due to the destruction of NAD of the phagocytizing cell by streptococcal



NADase. Since there is an indication in the literature that Ehrlich carcinoma ascites cells are capable of phagocytosis[4], it seemed of interest to examine the effect of tubercle bacilli grown *in vivo*, coated with NADase, on Ehrlich carcinoma ascites cells and to compare it with that of the tubercle bacilli grown *in vitro*. This communication is a preliminary report of these investigations.

Tubercle bacilli grown *in vivo* (*LH37Rv*) were obtained as previously described[5]. The *in vitro* grown bacteria, *M. tuberculosis H37Rv*, were obtained from 10–15 day cultures in albumin medium from which 'Tween-80' was omitted. The bacilli were collected by centrifugation, washed and homogenized in a 'Teflon' grinder. *H37Rv* and *LH37Rv* cells were suspended in 0·1 M phosphate buffer, *p*H 7·2 to which bovine albumin fraction V (Armour Pharmaceutical Co.) was added to 0·6 per cent final concentration. Proliferation of contaminants was prevented by addition of dihydrostreptomycin sulphate (100 μg/ml.) and penicillin (100 units/ml.). During the experiments, the bacterial suspensions were stored in the cold (2° C). The experiments were conducted on groups of 5–8 Swiss albino mice weighing 20–22 g. These were injected intra-abdominally with $1{\cdot}5 \times 10^6$ Ehrlich carcinoma ascites cells in 0·2 ml. of 0·1 M phosphate buffer, *p*H 7·2. Twenty-four hours afterwards the groups of mice were injected intra-abdominally with 0·2 ml. of 0·2 mg dry weight of tubercle bacilli grown *in vivo* and *in vitro*. In some experiments, the mice were given a second injection of tubercle bacilli, three to four days after inoculation with ascites cells. In order to prevent proliferation of the injected tubercle bacilli, dihydrostreptomycin sulphate (2 mg/mouse) was administered every second day subcutaneously. The control mice were also given the suspending medium and antibiotic treatment. Seven to eight days after the beginning of the experiment the mice were killed and the tumour cells collected from the peritoneal cavity by careful washing with a balanced salt solution containing heparin (3 units/ml.). The cells were counted in a counting chamber and examined by phase contrast microscopy.

Reduction in the No. of EAC (%)	83·1	90·5	17·4	51·3	

The results of a typical experiment are presented in Table 1. It can be seen from the table that injection of tubercle bacilli grown *in vivo* into mice bearing Ehrlich carcinoma ascites cells led to a marked reduction in the tumour cells, amounting to 83 per cent after a single injection and to 91 per cent after two injections. Microscopic examination of the remaining cells showed a high percentage of disintegrated cells. Vacuolation of the cellular cytoplasm was clearly defined and the nuclear membrane dissolved (Fig. 1). On the other hand, injection of tubercle bacilli grown *in vitro* had a considerably smaller effect on the tumour cells. The reduction in the number of tumour cells after one injection amounted to 17 per cent and after two injections to 51 per cent.

a *b*

Fig. 1. (*a*) Ascites cells from a control mouse; (*b*) ascites cells from a mouse treated with *LH37Rv*

Although the results of these experiments are in keeping with our hypothesis on the role of NADase in phagocytosis, we have not yet a direct confirmatory evidence for the tubercle bacilli entry into the ascites tumour cells. The mechanism by which the tubercle bacilli grown *in vivo* exert their effect on the Ehrlich carcinoma ascites cells is now being examined.

VIROLOGY

Murine Infection with Reovirus Type 3 and the Runting Syndrome

The purpose of this communication is to direct attention to the similarity, in clinical and pathological findings, of infant mice infected with reovirus type 3 and infant mice which develop as runts following the inoculation of immunologically competent lymphoid cells.

An examination of the literature on runt disease reveals a clinical and pathological picture of great variability. A general pattern of agreement is emerging and it is apparent that variations may be ascribed to cell dosage, route of inoculation, time of inoculation, source of lymphoid cells, species of animal, and the genetic constitution of host and donor. In mice the following features have been stressed: retardation of growth, an ataxic gait, diarrhœa, hunched posture, facial œdema, oily hair effect, jaundice, and alopecia[1]. Up to 90 per cent of mice may show focal, necrotic, coagulative liver lesions[1]. Some investigators report that the thymus may appear normal in size and appearance[2]. Although hæmolytic anæmia with a positive Coombs's test, leucopænia and splenomegaly have frequently been observed, these are not an invariable accompaniment of runting[2].

The clinical and pathological features of reovirus type[3] infection of mice have been described in some detail[3–5] and closely resemble the runting syndrome. The clinical syndrome of reovirus infection has only been demonstrated in infant mice less than five days of age and usually comprises retardation of growth, oily hair effect, diarrhœa, alopecia, jaundice, an ataxic mincing gait, and hunched posture. Although all mice show focal necrotic, coagulative liver lesions, the thymus appears normal[5]. There is, also, following intraperitoneal inoculation, a peritoneal ascites containing large numbers of primitive lymphoid cells.

These similarities may be considered alongside the observations that (1) polyoma virus may cause runting and anæmia[6]; (2) mouse hepatitis viruses have been associated with runting[7]; (3) cytomegalic inclusion

disease virus infection of infants may result in sequelæ which have been confused with erythroblastosis fœtalis[8]; (4) reovirus infections of humans appear to be mainly in infants; (5) the reovirus-induced hepatic lesions closely resemble those seen in immunological liver injury.

It would thus appear that further exploration of virus infection of the immunologically immature should be made to determine whether such infection will permit the establishment of a clone of cells which can react against the host. Thoughts have already been expressed[9] as to the possible mechanisms involved following the induction of various runting syndromes in mice.

In addition, the possibility that the lymphoid cells may be a source of mouse viruses cannot be entirely excluded.

This investigation was supported by U.S. Public Health Service research grant No. *E.*4627 from the National Institutes of Health.

Incorporation of 5-Iodo-2′-deoxyuridine into the Deoxyribonucleic Acid of Vaccinia Virus

The *in vitro* development of animal viruses containing deoxyribonucleic acid, such as vaccinia or herpes simplex, is inhibited by the thymidine analogue 5-iodo-2′-deoxyuridine (IUdR), whereas RNA-containing viruses are not affected[1]. This reagent has also been used successfully for the *in vivo* treatment of herpes[2] and vaccinia[3], and on tumours induced in hamsters by human adenovirus[4]. The mechanism of viral inhibition by IUdR is under investigation in these laboratories. Previous investigations[5] suggest that one possible mechanism may be that replacement of thymidine by IUdR in viral DNA renders the virus non-infective. It has been shown that IUdR has no direct inactivating effect on vaccinia virus particles *in vitro* (unpublished results). This communication presents evidence for the incorporation of IUdR into the DNA of vaccinia virus.

IUdR labelled with iodine-125 was synthesized by the method described previously[6] and had a specific activity of $3{\cdot}8 \times 10^5$ c.p.m./μmole. All radioactive measurements were made using a well-type γ scintillation counter.

Labelled vaccinia virus was prepared as follows. The chorioallantoic membranes of 12-day chick embryos were dropped with 0·1 ml. of antibiotic saline (0·9 per cent sodium chloride, M/100 phosphate buffer, *p*H 7·2; 1,000 units of penicillin and 0·1 mg of streptomycin/ml.). Four mg of IUdR-I^{125}, suspended in 5 per cent gelatin at a concentration of 10 mg/ml., were dropped on to each chorioallantois. The eggs were rocked on various axes to spread the reagent as evenly as possible. Previous experiment had shown that this amount of IUdR reduced the average number of viral pocks by 50–80 per cent, but had no effect on the viability of the embryos. Approximately 40 min later, each egg was inoculated with 1,000 pock-forming units of the fully egg-adapted Levaditi strain of vaccinia virus. At the same time, control virus was inoculated into eggs that had received antibiotic saline instead of IUdR. The chorioallantoic membranes were removed from treated and control eggs after incubation for 40 h at 37°, and washed in large volumes of antibiotic saline. It was observed that membranes treated with IUdR showed an average of approximately 100 very small, faint pocks, whereas control virus membranes were uniformly covered with typical confluent hæmorrhagic pocks.

The virus was extracted and purified from IUdR-treated, and from control membranes, by a modification of the fluorocarbon method described by Epstein[7]. The final supernatant fluids were strongly opalescent, and examination in the electron microscope (tungsten shadowing) revealed virus particles only. In several experiments a small proportion of flat ovoid structures, of similar dimensions to normal vaccinia particles, was seen in IUdR-treated virus preparations. These structures appeared devoid of internal nucleoid. The concentration of purified virus particles from IUdR-treated membranes was approximately 10 per cent of that from an equal number of control membranes. The infectivity titres of the purified IUdR and control virus samples were $3{\cdot}5 \times 10^6$ and $4{\cdot}3 \times 10^7$ pock-forming units/ml., respectively. Both samples gave rise to typical vaccinia pocks.

The purified IUdR-treated virus was then washed three times by centrifugation with large volumes of antibiotic saline to remove the relatively large amounts of RNA that are present after fluorocarbon treatment. The final washing contained no detectable radioactivity or material absorbing at 260 mμ. A small proportion (0·01 per cent) of the radioactivity found in the unwashed virus preparation was associated with the final viral pellet, and this proportion remained constant on further washing. The washed pellet was resuspended in absolute ethanol for several days at 4°, deposited by centrifugation, extracted with 1 : 1 ethanol-ether, and dried *in vacuo*. The viral pellet was then resuspended in 'Marmur' citrate-saline containing 2 per cent 2-mercaptoethanol and stirred for 20 h at 4°. The suspension was stirred for 6 h at 40° with pronase, and the DNA extraction continued as described previously[8]. The first two extracts contained 98 per cent of the original radioactivity, whereas only 2 per cent remained in the deposited viral 'debris'. Previous experience has shown that 90–95 per cent of vaccinia DNA is released in these extracts[8].

The two DNA extracts were pooled and purified further by density-gradient centrifugation. Sufficient cæsium chloride was added to bring the density to 1·70 g/ml., and the mixture centrifuged for 48 h at 38,000 r.p.m. in the Spinco *SW* 39 head. Fractions were collected by dripping from the bottom of the tube, and the radioactivity of each sample (10 drops) was determined. In a total of five separate runs, the radioactivity was banded at density levels of 1·71–1·73 g/ml. These bands were considerably broader than were those obtained with normal vaccinia DNA, 90 per cent of which bands sharply at a density of 1·71 g/ml.[9]. It is possible that incorporation of the base analogue in varying amounts causes density heterogeneity in the viral DNA. It was observed that counts of the γ-radiation derived from iodine-125 are reduced by about 80 per cent in solutions of cæsium chloride of this density.

Fractions obtained from the density-gradient centrifugation that showed high radioactivity were pooled, dialysed to remove cæsium chloride, and the presence of DNA was confirmed by a positive indole reaction. The ratio of the ultra-violet absorption (260/280 mμ) of this preparation of DNA was 1·747. The specific activity of the DNA was $5{\cdot}4 \times 10^4$ c.p.m./μmole of mono-nucleotide.

That IUdR was indeed a component of the DNA polymer was established by the following procedure. The radioactive DNA plus added non-radioactive DNA were hydrolysed to mono-nucleotides[10] and separated by ion exchange chromatography[11]. The eluates were examined for ultra-violet absorption at 260 mμ in a Beckman spectrophotometer, and for γ-radiation in a well-type scintillation counter. The peak of the radioactivity was found in an area known to be associated with 5-iodo-2′-deoxyuridylic acid and overlapping with deoxyguanylic

acid. The mixture of these two nucleotides was adsorbed on a column of 'Dowex-1' (chloride form), eluted with hydrochloric acid gradient, lyophilized, dissolved in water, and subjected to paper chromatography (Whatman No. 1; solvent, *n*-butanol : acetic acid : water, 5 : 2 : 3). The R_F of the radioactive area coincided with a known preparation of 5-iodo-2′-deoxyuridylic acid (R_F 0·16) and was separated from deoxyguanylic acid (R_F 0·05). Thus, it was established that the radioactivity derived from IUdR-^{125}I was present in the DNA-polymer and in nucleotide form.

It has been shown that IUdR is incorporated into the DNA of mammalian, bacterial and plant cells and that it specifically replaces the thymidine component. It was concluded from the present experiments that IUdR was incorporated into vaccinia virus DNA, and that 18 per cent of the viral DNA-thymidine was replaced by the analogue. Base ratios and extinction values for vaccinia virus DNA used in the calculations have been reported previously[12]. The significance of the observed incorporation of IUdR into the DNA of vaccinia virus in relation to the anti-viral activity of this analogue remains to be elucidated.

SOIL SCIENCE

Age of the Youngest Hydrated Halloysite in Kyushu

It has been well established that allophane formed from volcanic ash is followed by crystallization to hydrated halloysite in some circumstances. How many years are needed for the formation of hydrated halloysite in Nature?

A buried surface soil containing hydrated halloysite would offer a suitable sample for dating the mineral by means of radiocarbon measurements, if the soil contains enough organic carbon and has been isolated from biotic activity since the soil was covered with ash. Simultaneously with weathering of volcanic ash, organic matter will start to accumulate in the surface layer of the ash soon after deposition. This accumulation of organic matter would be stopped by any thick cover of ash that later fell, but the weathering of ash would still go on. So the age of volcanic ash in a previous surface layer can be estimated by the content of carbon-14 in the organic matter, provided that the period of time of carbon accumulation is negligibly short as compared with the ash-age.

In this respect, the mantle of volcanic ash on Aso Volcano in Kyushu Island, laid down as a series of showers since the later period of Pleistocene, would offer suitable samples for investigation. The ash-mantle is usually several metres thick, often including former surface soil layers that are easily distinguishable from over- and underlain layers by their high humus content. Clays of upper layers of a profile, less weathered ones, are mostly composed of allophane without kaolin, while those of lower layers, more weathered ones, tend to contain predominant hydrated halloysite with more or less allophane. If the latter layers contain organic matter, such as remains of plants from those days when the layers were on a surface, they would qualify as samples.

Examined samples were collected from a profile which is located on a gentle slope at the western foot of the central cone of Mt. Aso (Choyo, 32° 53′ N., 131° 0′ E.). The profile is about 8 m thick, and 17 layers at least were discernible[1]. X-ray and differential thermal analyses revealed that four upper layers contain predominantly allophane in the clay fraction but with no kaolin, and that the fifth layer (depth: 140–190 cm) is the uppermost one containing hydrated halloysite, the content of which was estimated to be about 33 per cent of the clay fraction (-2μ) by allocation of chemical and dehydration data and cation-exchange capacity delta-values to its constituent minerals (Table 1). This hydrated halloysite is evidently youngest in the Aso district, and probably in Kyushu. The mineral shows similar X-ray diffractive, differential thermal, and electron microscopic properties to the hydrated halloysite derived from volcanic ash and pumice already reported by several workers. That is, the mineral exhibits spherules or curled laths in shape and a low crystallinity. The organic carbon of this layer was calculated to be 8,650 ± 200 years old by measurements of radiocarbon by Prof. Kigoshi at Gakushuin University in Tokyo. This value undoubtedly represents an average of organic carbon accumulated in the layer while it was on the surface.

Table 1

Location	Horizon	Depth (cm)	Organic carbon (%)	In clay fraction: Allophane (%)	In clay fraction: Hydrated halloysite (%)
Choyo	1	0–30	8·2	67	0
	2	30–80	2·4	75	0
	3	80–90	1·2	73	0
	4	90–140	1·7	68	0
	5	140–190	11·0	37	33
Kanoya	1	0–30	5·6	70	0
	2	30–70	12·1	72	0
	3	70–130	1·8	80	0
	4	130–175	7·1	74	0
	5	175–225	2·5	75	0
	6	225–275	4·0	30	35

The period of the carbon accumulation could be roughly estimated from the carbon content of the layer. Since the bulk density of this layer is 0·6, its organic carbon amounts to 330 tons/hectare. Assuming that the carbon was accumulated at 1 ton/hectare/year and that no loss of carbon occurred following annihilation of vegetation due to the ash-cover, the flourishing period of vegetation comes to 330 years. Although the second assumption is not the case in a strict meaning, the decomposition of humus in buried Ando soils is undoubtedly extremely slow. It would be difficult to settle the rate of carbon accumulation in ancient days. However, there is some evidence that 2 tons carbon/hectare/year or even more could be accumulated in volcanic ash soils[2], and consequently it might be probable that 330 tons carbon was accumulated in a hectare even in a shorter time than 330 years. According to the foregoing, it would be concluded that the hydrated halloysite of the fifth layer was derived from the ash that fell between 8,000 and 9,000 years ago, and is the youngest in the Aso district.

In comparison with this, another volcanic ash profile was examined in the same way. The profile is located on the Kasanohara tableland (Kanoya, 31° 24′ N., 130° 52′ E.). Although it has little connexion with the ash of Aso Volcano, origins of ashes and pumices consisting of the profile are still obscure. Three former surface layers are observed in the profile, that is, 2nd, 4th, and 6th in Table 1.

Hydrated halloysite was not found as far as the fifth layer (depth: 225–275 cm), and the sixth layer, the third former surface layer, was the uppermost one containing the mineral. Namely, the hydrated halloysite of this layer is youngest in the profile at Kanoya. However, this layer is beyond the limits of carbon-14 dating, that is, older than 30,000 years. The particles of the mineral are not so different in shape from those of Choyo, and show spherules, curled laths, and short tubes. The particles of Choyo are mostly composed of spherules, while tubes are dominant in the Kanoya mineral. This might explain the metamorphosis of spherules into tubes. Kuwano *et al.*[3] considered that the layer belongs to the lower loam of the Pleistocene Epoch. This would mean that it is about 30,000 years old or more and is consistent with the radiocarbon measurements.

We wish to thank Prof. Kunihiko Kogoshi for dating humus.

PSYCHOLOGY

Ipsilateral Confusion in 2-Choice and 4-Choice Responses with the Hands and Feet

The experiments to be described here suggest that confusion occurs between ipsilateral responses in certain choice-reaction tasks. This finding has apparently not been reported before.

In the first of the present 4-choice experiments, the subject responded to a positional display consisting of four neon indicator bulbs set in a black screen so as to form a square 4 in. × 4 in. The subject sat facing the screen, and responded by pressing morse keys with the hands and feet. Details of the apparatus will be given in a later communication. The required response to the top right signal was the right hand, to the bottom right signal the right foot, and similarly on the left side. 45 subjects each responded to 80 signals, 20 for each foot and each hand, presented in a random order. 513 errors were made, giving a total error rate of 14·25 per cent. The distribution of these errors is given in the matrix in Table 1. 98·1 per cent of the errors were ipsilateral (for example, right-hand responding to right foot signal, left foot responding to left-hand signal, etc.). There were no diagonally opposite errors (for example, left foot responding to right-hand signal, etc.).

Two further 4-choice experiments were afterwards carried out with slightly altered displays, one with the signals in the form of a square 1¼ in. × 1¼ in., and the other with them in the form of a rectangle, 4 in. (vertical dimension) × 1¼ in. In each experiment 13 subjects each responded to 800 signals, 200 for each foot and each hand, presented in a random order. Results were obtained similar to those of the first experiment. With the small square display, in the first half of the experiment (that is, the first 400 responses for each subject), 97·9 per cent of the errors were ipsilateral (total error rate 11·0 per cent), and in the second half 97·1 per cent were ipsilateral (total error rate 11·3 per cent). With the rectangular display, in the first half 97·6 per cent of the errors were ipsilateral (total error rate 9·6 per cent), and in the second half 85·3 per cent were ipsilateral (total error rate 11·9 per cent).

Table 1. Errors made in Four-Choice Reaction Task with Hands and Feet

		Errors			
		RH	LH	RF	LF
Correct Response	RH		2 (2) 0·2%	105 (42) 11·7%	0
	LH	4 (4) 0·4%		0	139 (42) 15·4%
	RF	116 (38) 12·9%	0		2 (2) 0·2%
	LF	0	143 (42) 15·9%	2 (2) 0·2%	

Down the side of the matrix is indicated the correct response. The columns across show the number of errors made to each signal by each of the other limbs. The figures in parentheses give the number of subjects contributing to the total ($N = 45$). Errors are also expressed as percentages of the total number of responses to each signal.

The same predominance of ipsilateral errors occurred again in a further 4-choice experiment, this time with tactile stimuli. The response movements were the same as in the three previous experiments, and tactile stimulation was provided by screws attached by an adjustable extension to the plunger of a solenoid. 12 subjects each responded to 800 signals, as in the second and third experiments. In the first half of the experiment 98·7 per cent of the errors were ipsilateral (total error rate 8·3 per cent); in the second half 85·5 per cent were ipsilateral (total error rate 6·2 per cent).

Two 2-choice experiments were carried out with the original square display (4 in. × 4 in.). Each was in three parts, with the two responses being either ipsilateral, contralateral or diagonally opposite. In the first, one of the two responses was always the right hand, the alternative being the right foot, left hand, or left foot, respectively. In the second, one of the two responses was the left foot and the alternative was the left hand, right foot, or right hand, respectively.

In each part of each experiment six subjects each responded to 300 signals over three sessions. In each session the three parts were presented in a different order. The mean reaction times for both the right hand and the left foot were least when the alternative response was the contralateral limb, and greatest when it was the ipsilateral (Table 2). In both cases analysis of variance showed that the differences were significant ($D < 0·01$). The number of errors was also greatest when the alternative response was ipsilateral.

Table 2. Variation in Two-Choice Reaction Times according to Alternative Response

	Alternative response		
	Contralateral	Diagonally opposite	Ipsilateral
Exp. 1	(LH)	(LF)	(RF)
Group mean right hand RT (ms)	281	290	316
Mean σ	38	42	**51**
Total errors	14	10	34
Exp. 2	(RF)	(RH)	(LH)
Group mean left foot RT (ms)	301	320	346
Mean σ	40	45	60
Total errors	18	22	56

These findings indicate confusion between ipsilateral hand and foot responses, leading either to errors between them, or to a lengthened reaction time when distinction between them is required. In the only previous experiment on reaction times that appears to be relevant, Davis[1] found no difference in the mean 2-choice reaction time between a situation in which the responses were made by the two hands, and one in which they were made by two fingers on one hand. This gives a warning against generalizing from the present findings to the conclusion that all ipsilateral responses are liable to be confused.

This work was carried out with the help of a research studentship from the Department of Scientific and Industrial Research. I thank Dr. J. A. Leonard, of the Medical Research Council's Applied Psychology Research Unit at Cambridge, for his advice.

FORTHCOMING EVENTS

(Meeting marked with an asterisk is open to the public)

Tuesday, October 1

INSTITUTION OF CHEMICAL ENGINEERS (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5·30 p.m.—Mr. J. H. Rushton: "Fluid Mixing in Theory and Practice".

Wednesday, October 2

INSTITUTE OF PETROLEUM (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. S. A. W. Thompson, Mr. S. R. Hills, Mr. M. P. H. Brown and Mr. A. Lewis: "Corrosion of Silver by Aviation Turbine Fuels".

BRITISH INSTITUTION OF RADIO ENGINEERS, MEDICAL ELECTRONICS GROUP (joint meeting with the INSTITUTION OF ELECTRICAL ENGINEERS, at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6 p.m.—Discussion on "Electronic Equipment for Medical Research—Build or Buy" opened by Mr. W. J. Perkins and Dr. G. H. Byford.

Thursday, October 3

UNIVERSITY COLLEGE, LONDON (in the Physiology Theatre, Gower Street, London, W.C.1), at 5 p.m.—Dr. B. Cinader (University of Toronto): "Some Aspects of the Interaction between Enzyme and Antibody"*.

INSTITUTE OF METALS (at 17 Belgrave Square, London, S.W.1), at 7 p.m.—Mr. J. W. Kirk: "Flash Radiography—a Potential Tool for Metallurgy"; Mr. J. C. Needham and Mr. A. A. Smith: "High-Speed Photography of Metal Transfer in Welding".

Friday, October 4

BRITISH MYCOLOGICAL SOCIETY (at The School of Pharmacy, Brunswick Square, London, W.C.1), at 11 a.m.—Scientific Papers.

INSTITUTION OF MECHANICAL ENGINEERS, EDUCATION AND TRAINING GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "How Should Engineering Education Take Account of Developments in the Newer Materials?—Item 2, Ceramics".

SOCIETY OF CHEMICAL INDUSTRY, FINE CHEMICALS GROUP (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Prof. D. H. R. Barton, F.R.S.: "Photo-Chemical Synthesis".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT LECTURER or LECTURER IN PURE MATHEMATICS—The Registrar, The University, Hull (October 5).

ASSISTANT LECTURER or LECTURER (with medical qualifications or a degree in physiology) IN PHYSIOLOGY at the University of the West Indies—The Secretary, Senate Committee on Colleges Overseas in Special Relation, University of London, Senate House, London, W.C.1 (October 7).

LECTURER IN PURE MATHEMATICS—The Secretary, The University, Edinburgh (October 7).

RESEARCH FELLOW (with a good degree, or equivalent, in any branch of science or engineering; a logical outlook, some knowledge of statistics; and preferably research experience) IN INFORMATION SCIENCE IN THE DEPARTMENT OF MANAGEMENT AND SOCIAL SCIENCES, for a four-year investigation of principles of information storage and retrieval—The Secretary, Northampton College of Advanced Technology, St. John Street, London, E.C.1 (October 7).

RESEARCH ASSISTANT (graduate in microbiology or biochemistry, preferably with research experience) IN THE DEPARTMENT OF BOTANY AND MICROBIOLOGY, to work on certain aspects of petroleum microbiology—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (October 11).

CHAIR OF PURE MATHEMATICS—The Registrar, The University, Manchester 13 (October 12).

CHAIR OF PHARMACOLOGY—The Registrar, University of Newcastle upon Tyne, 6 Kensington Terrace, Newcastle upon Tyne 2 (October 12).

LECTURER or ASSISTANT LECTURER IN CIVIL ENGINEERING—The Registrar, The University, Nottingham (October 12).

LECTURER or ASSISTANT IN PSYCHOLOGY at Queen's College, Dundee—The Secretary, University of St. Andrews, Queen's College, Dundee, Scotland (October 12).

ASSISTANT LECTURER (preferably honours graduate in zoology or physiology with suitable postgraduate experience) IN ANATOMY AND HISTOLOGY—The Registrar, The University, Nottingham (October 15).

CHAIR OF MATHEMATICAL STATISTICS—The Registrar, University of Sussex, Stanmer House, Stanmer, Brighton, Sussex (October 15).

DEMONSTRATOR (preferably honours graduate in animal physiology or animal husbandry) IN ANIMAL SCIENCE—The Registrar, The University, Nottingham (October 15).

RESEARCH FELLOW IN THE DEPARTMENT OF ELECTRON PHYSICS, to study the Hall Effect in compound semi-conductors above the melting point—The Assistant Registrar (Science), The University, Birmingham 15 (October 15).

ENTOMOLOGIST (with an honours degree in zoology, and preferably previous experience in research on pests of tropical crops), to undertake research on the insect pest problems in coffee throughout Kenya—The Senior Research Officer, Coffee Research Station, P.O. Box 4, Ruiru, Kenya (October 19).

LECTURER (with a degree in science or agricultural science and qualified in biometry, agricultural statistics or mathematical statistics) IN BIOMETRY at the University of Sydney, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 25).

SENIOR LECTURER IN PHARMACOLOGY at the University of Sydney, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 25).

ASSISTANT (honours graduate in physics or engineering) IN EXPERIMENTAL PHYSICS, to undertake teaching duties and assist in the planning of a 100-MeV electron linear accelerator facility for nuclear physics research—The Secretary of University Court, The University, Glasgow (October 31).

LECTURER IN PHILOSOPHY at Victoria University of Wellington, New Zealand, The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, October 31).

LECTURER or ASSISTANT LECTURER IN BIOCHEMISTRY at the University of Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (October 31).

LECTURERS or ASSISTANT LECTURERS IN ZOOLOGY at the University of Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (October 31).

LECTURERS (2) (with an honours degree in geography or equivalent qualifications) IN GEOGRAPHY at the University of Melbourne, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 31).

SENIOR LECTURER IN PHARMACOLOGY IN THE DEPARTMENT OF PHYSIOLOGY in the Faculty of Medicine, University of Natal/National Provincial Administration—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, October 31).

SENIOR LECTURER/LECTURER (with an honours degree in physics and evidence of research ability) IN THE SCHOOL OF PHYSICS, University of New South Wales—The Agent-General for New South Wales, 56/57 Strand, London, W.C.2; and the Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia (October 31).

SENIOR LECTURER IN BACTERIOLOGY at the University of Sydney, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, November 1).

CHAIR OF BIOCHEMISTRY at the Royal Free Hospital School of Medicine—The Academic Registrar, University of London, Senate House, London, W.C.1 (November 11).

LECTURER and an ASSISTANT LECTURER (with research interests in the high energy physics field) IN THE DEPARTMENT OF PHYSICS in the Faculty of Science—The Registrar, The University, Manchester 13 (November 15).

SENIOR LECTURER IN STATISTICS at the University of Melbourne, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, November 30).

ASSISTANT PROFESSOR (with postgraduate education equivalent to the Ph.D.) of ANIMAL NUTRITION—Head, Department of Animal Science, University of Alberta, Edmonton, Alberta, Canada (December 15).

ASSISTANT Lecturer (graduate in microbiology)—The Principal, National College of Food Technology, St. George's Avenue, Weybridge, Surrey.

ECOLOGIST (male, between 23 and 35 years of age, with a good honours degree in botany and two years postgraduate experience in ecology) in Western Nigeria, for ecological surveys and assessment of land potential—The Director of Recruitment, Department of Technical Co-operation, Eland House, Stag Place, Victoria, London, S.W.1, quoting Ref. RC. 213/106/01.

HEAD OF THE DEPARTMENT OF ENGINEERING (Grade II)—The Principal, North Devon Technical College and College of Further Education, Sticklepath, Barnstaple, North Devon.

ISOTOPE RADIOGRAPHER/TECHNICIAN (preferably qualified radiographer or candidate with experience of radiochemical laboratories) IN THE ISOTOPE SECTION OF THE PHYSICS DEPARTMENT, to assist with the clinical and laboratory applications of radioactive isotopes to medical problems—The House Governor, The London Hospital, Whitechapel, London, E.1.

PHYSICIST (preferably with experience in radiation dosimetry and/or work with linear accelerators), to join a team (under Prof. J. Rotblat) carrying out research on the effects of radiation—The Secretary, Physics Department, St. Bartholomew's Hospital Medical College, Charterhouse Square, London, E.C.1, quoting Ref. No. AC/288.

POST-DOCTORAL FELLOW, for work in the field of molten salt electrochemistry—Head, Department of Pure and Applied Chemistry, Northampton College of Advanced Technology, St. John Street, London, E.C.1.

RESEARCH ASSISTANT (with a general degree or G.C.E. "A" level in chemistry and/or laboratory experience of analytical biochemistry) AT THE CHESTER BEATTY RESEARCH INSTITUTE, Fulham Road, S.W.3, for work on biochemical characterization of human leukæmia—The Secretary, Institute of Cancer Research, 34 Sumner Place, London, S.W.7, quoting Ref. 301/B/136.

RESEARCH FELLOW (registered medical practitioner or science graduate with an interest in the behaviour and sampling of air-borne particles) IN THE DEPARTMENT OF BACTERIOLOGY AND SURGERY, to work on problems connected with hospital cross-infection—Clerk to the Governors, St. Bartholomew's Hospital, London, E.C.1, quoting Ref. AC/303.

Admit it: *we're talking sense*

We're talking about life assurance. We're talking, in fact, about the oldest mutual life office: the Society that laid the foundations of life assurance as it is known today. The 'Old Equitable', founded two hundred years ago, has this about it:

It has no shareholders. It pays no commission for the introduction of business. This is how life assurance was originally conceived; and in preserving these co-operative principles, the 'Old Equitable' provides life assurance at cost price.

The 'Old Equitable' is friendly and helpful; and it does a good job for your money. For example, a quarterly payment of £17.12.6 secures a man of 25 an assurance of £3,000 sharing in major profits and payable at death whenever that should occur. Such a policy taken out 50 years ago would this year yield over £10,000 on the death of the life assured. If you would like to know more about the many kinds of assurance that the 'Old Equitable' offers, please fill in the coupon below.

HEATHWAY
FOR GLASS WORKING LATHES

A 6¼ bore lathe of the latest design with foot drum control

All the HEATHWAY range of lathes have the following features:

★ **Robust Construction and lasting accuracy**
★ **Efficient variable speed and easily accessible controls**
★ **Smooth traverses essential to good glassworking**

May we send you details of our range of lathes and equipment

Write or phone:
The HEATHWAY MACHINERY CO., UXBRIDGE ROAD, HILLINGDON, MIDDX.

CLASSIFIED ADVERTISEMENTS

are charged at 12s. for the first line and 6s. per line thereafter. Lines in capitals or containing words in capitals 12s. per line. Semi-displayed £4 16s. per single column inch. Colour (orange) £15 extra. 1s. is charged for the re-direction of replies to advertisements with a box number.

ADVERTISEMENTS SHOULD BE ADDRESSED TO: T. G. Scott and Son, Limited, 1 Clement's Inn, Strand, London, W.C.2. Telephone: HOLborn 4743. Telegrams: Textualist, Estrand, London.

APPOINTMENTS VACANT

IMPERIAL CANCER RESEARCH FUND

TISSUE AND ORGAN CULTURE UNIT

Applications are invited for two appointments in the above Unit from graduates in medicine or biology:

1. *Experimental Pathologist.* Special experience of histochemistry an advantage. Salary in the range £1,595 to £2,475 per annum (plus London allowance) depending on qualifications and experience.
2. *Cell Biologist* with special experience in cell and/or organ culture techniques. Salary in the range £1,260 to £1,895 per annum (plus London allowance) depending on qualifications and experience.

The work is mainly concerned with the effects of growth factors on normal and tumour tissues but opportunities will be available to develop other lines of research.

Further particulars may be obtained from:
The Secretary,
Imperial Cancer Research Fund,
Lincoln's Inn Fields,
London, W.C.2,
to whom applications should be submitted not later than October 31, 1963.

UNIVERSITY OF NOTTINGHAM

ASSISTANT LECTURER IN ANATOMY AND HISTOLOGY

Applications are invited for the above post in the Department of Agriculture, Sutton Bonington, near Loughborough, to begin January 1, 1964. Preference will be given to honours graduates in zoology or physiology with suitable postgraduate experience. Salary scale, £1,000 by £50 to £1,150 per annum, plus superannuation and children's allowance.

Conditions of appointment and form of application, to be returned by October 15, 1963, from the Registrar, Nottingham University.

CHELSEA COLLEGE OF SCIENCE AND TECHNOLOGY

MANRESA ROAD, LONDON, S.W.3

READER IN BIOPHYSICS

Applications are invited for the newly created post of Reader in Biophysics. Salary within scale £2,295 to £2,760.

Further particulars may be obtained from the Clerk to the Governors, to whom applications should be sent (together with the names of two referees), by October 21, 1963.

NATIONAL COLLEGE OF FOOD TECHNOLOGY

ST. GEORGE'S AVENUE
WEYBRIDGE, SURREY

Principal: J. D. Mounfield, M.Sc.Tech., Ph.D., F.R.I.C.

Applications are invited for the post of Assistant Lecturer in the College from graduates in Microbiology. Facilities for research are available. Salary in accordance with the Burnham Committee scales for Establishments of Further Education (1961). Starting salary dependent on qualifications and experience.

Application forms (obtainable from the College) should be sent to the Principal as soon as possible.

UNIVERSITY OF MANCHESTER

Applications are invited for the post of Assistant Lecturer in Botany. Applicants should have specialized in mycology but interests in other aspects of cryptogamic botany and plant pathology would also be an advantage. Salary on a scale £1,000 to £1,150 per annum with membership of F.S.S.U. and children's allowance scheme.

Applications should be sent not later than October 5, 1963, to the Registrar, the University, Manchester, 13, from whom further particulars and forms of application may be obtained.

Central Electricity Generating Board

INFORMATION SERVICES

TRANSLATORS/ABSTRACTORS

Applications are invited for posts as Information Assistants (Translators/Abstractors) in the Information Services at Headquarters, at present located in London, S.E.1, but moving to new offices near St. Paul's in 1964.

The successful candidates will be required to scan and assess a wide range of foreign technical literature, to select articles and abstract them. They will also be required to prepare or edit technical translations and assess foreign papers before translation.

Applicants should be competent German, Russian or French translators, preferably with English as mother tongue, and a sound scientific or technical education not less than pass degree standard. Experience in information work will be an advantage, but candidates with a suitable technical and linguistic background wishing to enter this field will be considered.

● **Salaries on one of the following grades according to qualifications and experience: £1,130 to £1,340 or £1,260 to £1,440 per annum.**

Applications stating age, qualifications, experience, present position and salary to N. Berryman, Personnel Officer (Headquarters), 24/30 Holborn, London, E.C.1

UNIVERSITY OF EDINBURGH

DEPARTMENT OF MEDICAL PHYSICS

LECTURESHIP

Applications are invited for the post of Lecturer in the above Department. Salary scale: Lower £1,250 by £110 to £1,690; Higher £1,805 by £115 to £2,150 by £110 to £2,700 per annum, with placement according to qualifications and experience, and with superannuation benefit and family allowance where applicable. The successful applicant will include among his duties those of University Radiation Protection Officer and will be expected to undertake and supervise research in this and related fields. The successful applicant will be expected to take up duty in October, 1963, or as soon as possible thereafter.

Further particulars may be obtained from the undersigned, with whom applications (six copies), giving the names of two referees, should be lodged not later than October 12, 1963.

CHARLES H. STEWART,
Secretary to the University.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE

DEPARTMENT OF BOTANY AND MICROBIOLOGY

Applications are invited for a post of Research Assistant at a salary of £900 per annum. The post will be available for three years, renewable annually. The successful applicant will be required to work on certain aspects of petroleum microbiology and should be a graduate in microbiology or biochemistry, preferably with research experience.

Applications, with the names of two referees, should be submitted to the Registrar, University College, Cathays Park, Cardiff, not later than October 11, 1963.

UNIVERSITY OF READING

DEPARTMENT OF GEOLOGY

Senior Technician (Grade II) required for the teaching section. Ability to supervise and organize technicians and technical services essential. Experience of similar work desirable.

Applications to the Assistant Bursar, The University, Reading.

UNIVERSITY OF MANCHESTER

Applications are invited for a Chair in Pure Mathematics, in succession to Professor Kurt Mahler, F.R.S. (It has already been announced that Professor M. H. A. Newman, F.R.S., Fielden Professor of Pure Mathematics, is to be succeeded in October, 1964, by Dr. J. F. Adams, at present Reader in Mathematics in the University.) Salary not less than £2,900 per annum. Membership of F.S.S.U. and children's allowance scheme.

Applications (one copy only), giving full details of qualifications, publications, experience, etc., and the names and addresses of at least three persons to whom reference may be made, should be sent not later than October 12, 1963, to the Registrar, the University, Manchester 13, from whom further particulars may be obtained.

DERBY AND DISTRICT COLLEGE OF TECHNOLOGY

Principal: Dr. T. Heap, M.Sc., F.R.I.C., A.M.B.I.M.

Applications are invited for the post of Head of Department of Chemistry, Grade III, duties to commence on January 1, 1964. Candidates must have a good honours degree together with teaching, industrial and/or research experience and should be capable of directing the postgraduate courses and research work in the department. Salary in accordance with Burnham Technical Scale, Grade III, £2,170 to £2,365.

Application form, returnable by October 4, and further particulars may be obtained from the Registrar, Derby and District College of Technology, Kedleston Road, Derby.

SENIOR VACANCIES EXIST IN BUSY RESEARCH laboratory for trained technicians and recently qualified graduates to work in the fields of biochemistry, haematology and histology and to take part in research analytical problems. Excellent opportunities exist for further study and training in all laboratory disciplines. Salaries commensurate with age and experience will be agreed prior to appointment.—Apply, in strict confidence, quoting reference BC/JSL, to the Administrative Officer, Huntingdon Research Centre, Huntingdon.
